LC20 2 A molecular approach to digital electronics* JORGE M. SEMINARIO, *University of South Carolina* Molecular electronics is a new field in which single molecules are proposed as the key components to be used in computational devices. Single molecules having electronic transport barriers strategically located could serve as switches and logical devices. Though numerous obstacles remain, the possibility of a huge increase in computing performance offers an exciting impetus to the development of molecular-scale electronic architectures for future ultracomputing. A molecular-based paradigm using molecular electrostatic potentials is outlined for newly synthesized molecular systems. Ab initio methods, including density functional theory, are used to select and substantiate the efficacy of the proposed devices, as well as to interpret related experiments. [1] J. M. Tour, M. LC20 3 Thermoactivated magnetization reversal in nanocylinders: asymptotical analysis VIATCHESLAV DOBROVITSKI, *Ames Laboratory, Iowa State University, Ames, IA 50011* BRUCE N. HARMON, *Ames Laboratory, Iowa State University, Ames, IA 50011* MIKHAIL KATSNELSON, *Institute of Metal Physics, Ekaterinburg 620219, Russia* Study of magnetization reversal is of topical interest for prospective high-density magnetic memory devices. At usual operating temperatures, the main physical effect governing stability of the information in such a device is the spontaneous reversal due to thermal fluctuations, which activate the system and allow it to overcome the energy barrier. We present an analytical study of thermoactivated magnetization reversal in a magnetic cylinder, with a radius on the order of a few tens of nanometers (nanocylinder). The realistic case of a fairly thick (basically, 3-D) cylinder is considered, where the reversal proceeds via vortex formation (curling mode). For the experimentally important case of an external field close to the critical field, exact analytical expressions for the potential barrier height and the micromagnetic structure of the critical nucleus are found. It is shown that when the external field is sufficiently close to the critical value, the reversal nucleation rate strongly depends on the cylinder size. Our results can explain unusual features detected in experiments. The method proposed is rather general and can be extended to similar problems.

14:15

LC20 4 Quantum Transport through Atomic Scale Junctions JEREMY TAYLOR, *McGill University* A quantitative prediction of the quantum transport properties of atomic scale devices requires detailed knowledge of the microscopic degrees of freedom. To this end, we have developed an *ab initio* method for calculating transport properties of atomic scale devices. Our method combines quantum molecular dynamics (QMD), evaluation of the single electron scattering potential within density functional theory, and finally the solution of the three-dimensional quantum scattering problem. With this method, we are able to calculate the conductance and capacitance of a device from first principles. Using QMD, we are able to study fluctuations in conductance and capacitance due to fluctuations of the atomic structure. We have studied various atomic scale devices including Al, Si, and C systems. The work reported here is in collaboration with Prof H. Guo of McGill University and Prof J. Wang of the University of Hong Kong.

LC20 5 pH Assisted Adsorption Studies of Nanosilicon. DEBJIT CHATTOPADHYAY, *Polymer Science Program, Nanomaterials Optoelectronics Laboratory, University of Connecticut* THOMAS PHELY-BOBIN, *Polymer Science Program, Nanomaterials Optoelectronics Laboratory, University of Connecticut* FOTIS PAPADIMITRAKOPOULOS, *Department of Chemistry, Polymer Science Program, Nanomaterials Optoelectronics Laboratory, Institute of Material Science, University of Connecticut, Storrs, CT 06269-3136* Nanosized silicon has been the focus of much attention in recent years. Recently our labrotary has reported a high energy nanomilling, sonication, centrifugation process for the fabricating stable colloidal nansize silicon particles in the range of 7-40 nm with a size distribution of about 25can lead to nanocomposities with refractive index as high as 3.2 with in-

creased transparency in the red part of the spectrum. The oxidation of these particles leads to their spontaneous adsorption on to different substrates such as glass and gold. This self assembly process leads to the formation of transparent ultrathin films of Si/SiO_x nanocomposites. A careful control of pH allows their readsorption in the substrate after their removal by sonication or mechanical friction. It has been found that at a pH of 5.5 these nanoparticles adsorb strongly on the glass surface. However at a pH of around 8 these particles form a stable suspension and do not adsorb.

14:39

LC20 6 Electron Transfer in Redox-Active Enzymes MINGSHAW WU, *Department of Physics, Princeton University* JEFFREY CARBECK, *Department of Chemical Engineering, Princeton University* LYDIA SOHN, *Department of Physics, Princeton University* Using electron-beam lithography, we are able to fabricate metallic nanoelectrodes, 20 nm wide and less than 10 nm apart. Electrodes at these length scales can potentially probe such molecular systems as redox-active enzymes. However, the challenge is to interface the electrodes with the molecule of choice for direct electron transfer. We will discuss not only our technique for fabricating nanoelectrodes but also our efforts in interfacing them with select redox-active enzymes.

14:51

LC20 7 New 4× 4 Matrix Method for Light Propagation in General Optically Active Media* HAIJUN YUAN, *Liquid Crystal Institute, Kent State University* E WEINAN, *Courant Institute of Mathematical Sciences, New York University* TAMAS KOSA, PETER PALFFY-MUHORAY, *Liquid Crystal Institute, Kent State University* Explicit analytic solutions of Maxwell's equations in general linear optical media enable us to describe light propagation in terms of the amplitudes of the four propagating modes. Closed form expressions are obtained for the 4× 4 propagation matrix; this formalism can be used to describe light propagation in lossy, biaxial, gyrotropic and magneto-chiral dichroic materials, and model the response of devices such as magneto-optical components, liquid crystal displays and polarizers. We provide illustrative examples, and compare our approach with other methods currently in use.

LC20 8 Transport through a Finite Hubbard Chain Connected to Reservoirs AKIRA OGURI, *Osaka City University, Japan* The dc conductance, g_N, through a finite Hubbard chain of size N ($= 1, 2, 3, \ldots, 50$) connected to semi-infinite noninteracting leads is investigated at $T = 0$ in an electron-hole symmetric case. We calculate a spatial dependence of the self energy analytically at $\omega = 0$ within the second order in the Hubbard U, and obtain an inter-site Green's function G_{N1}, with which g_N can be determined, via the Dyson equation. The results depend strongly on whether the number of the interacting sites N is even or odd, and the obtained g_N is an oscillatory function of N. For odd N ($= 2M + 1$), a perfect transmission occurs, $g_{2M+1} \equiv 2e^2/h$, independent of the values of U. This fact remains valid even when the higher-order terms are included, and it may be attributed to the appearance of a Kondo resonance at $\omega = 0$. On the other hand, for even N ($= 2M$), the envelope of the results g_{2M} decreases with increasing M, and converges to a finite constant which depends on U; the value of the constant decreases smoothly with increasing U. All these results, obtained at $T = 0$ keeping N to be finite, show a metallic behavior in spite of an electron-hole symmetric case. These behaviors are essentially owing to the presence of the noninteracting leads, which make a quasi-particle description valid for low-energy states at $\omega \ll \hbar v_F/L$, where v_F is the Fermi velocity and $L = Na$ with a being the lattice constant.

LC20 9 Two and Three Dimensional Imaging of Buried Integrated Circuit Structures* S.P. FRIGO, I. McNULTY, C.C. RETSCH, Y. WANG, *Advanced Photon Source, Argonne National Laboratory* Z. LEVINE, A. KALUKIN, *National Instutute of Standards and Technology* M. KUHN, *Intel Corporation* We have made two- and three-dimensional images of interconnect junctions in a two-level integrated circuit. The junctions were buried in an SiO_2 matrix. The circuit, fabricated using common manufacturing techniques, contained Si, O, Al, W, N and Ti. We acquired two-dimensional projection images for thirteen different sample rotations. The projections were obtained by scanning the sample in a 150-nm-diameter focused soft x-ray beam spot and collecting the transmitted photons. A three-dimensional reconstruction was made from the projection data using a standard algorithm with a resulting volume resolution of 300 nm^3. The two-level circuit structure is clearly shown in the reconstruction. Our results indicate that computed x-ray nanotomography will be a useful tool for non-destructive inspection of buried objects and interfaces in current- and next-generation microelectronic devices. We will be implementing the technique to image void defects caused by electromigration.

LC20 10 Surface-Plasmon-Enhanced Optical Transmission of Novel 2D Metal Structures D. E. GRUPP, *NEC Research Institute* H. J. LEZEC, *ISIS, Louis Pasteur University & Micrion Europe GmbH* T. THIO, *NEC Research Institute* H. F. GHAEMI, *NEC Research Institute & Physics Dept., Brooklyn College* P. A. WOLFF, *NEC Research Institute & Physics Dept., MIT* T. W. EBBESEN, *NEC Research Institute & ISIS, Louis Pasteur University* The optical transmittance of a subwavelength aperture in a metal film has recently been shown to be enhanced by over three orders of magnitude when the apertures are configured in a regular array. This enhancement is due to a coupling of the incident photons to surface plasmons, which are the collective modes of electrons within a skin-depth of the metal. In order to further understand the physics underlying the high transmission efficiencies, we have investigated the transmittance of perforated metal films with novel geometries.Results of these experiments will be presented, and possible applications will be discussed.

SESSION LC21: KONDO PHYSICS & ONE DIMENSIONAL ELECTRON TRANSPORT
Tuesday afternoon, 23 March 1999

LC21 1 Exploring Kondo Physics With a Single-Electron Transistor D. GOLDHABER-GORDON, RESJ. GO, *MIT* HADAS SHTRIKMAN, D. MAHALU, U. MEIRAV, *Weizmann Institute of Science* M.A. KASTNER, *MIT* For half a century the influence of magnetic impurities on the low temperature thermodynamic and transport properties of a host metal, known as the Kondo effect, has been an active field of investigation. The essential physics is contained in the Anderson model of a single magnetic impurity strongly coupled to a Fermi sea of electrons. This model has served over the years as a testing ground for nonperturbative calculational techniques. Experimental verification of many of the theoretical predictions has not been possible because of the limited control over parameters in bulk metal systems. A Single-Electron Transistor is a small droplet of localized electrons coupled to leads by tunnel barriers. It has been predicted that this system can be described by the Anderson model and thus should display the Kondo effect in the presence of an unpaired spin on the droplet. This has been observed and confirmed experimentally. We will discuss how by tuning the unpaired electron's energy with respect to the Fermi energy in the leads we have been able to confirm quantitatively the predicted effect on electronic transport in the Kondo regime. We have also observed the crossover to the mixed valence regime. (D. Goldhaber-Gordon *et al.*, *PRL*, Dec. 7, 1998.)

13:27

LC21 2 Fano Lineshapes in Electronic Transport Through a Single-Electron Transistor J. GÖRES, D. GOLDHABER-GORDON, S. HEEMEYER, *MIT* HADAS SHTRIKMAN, D. MAHALU, U. MEIRAV, *Weizmann Institute of Science* M.A. KASTNER, *MIT* The Fano effect is seen in atomic or nuclear scattering experiments when the incoming particle can scatter either directly into the continuum or through a resonant quasibound level. The interference between these paths leads to characteristic asymmetric lineshapes. We have observed Fano lineshapes in electronic transport through a Single Electron Transistor (SET), which is a small droplet of localized electrons coupled to leads by tunnel barriers. Whenever a discrete energy level of the localized electrons is degenerate with the Fermi level in the outside leads, resonant tunneling occurs. The Fano interference effect arises in this system because electrons can traverse the SET coherently either through a resonant level or by higher order tunneling through an off-resonant level. For a pronounced effect to be visible both levels must be strongly coupled to the leads, which is only possible for the unusually small SETs that we have been studying. By changing the coupling of the discrete levels to the leads we are able to tune the resonances from the asymmetric Fano regime to the more familiar symmetric Breit-Wigner regime.

13:39

LC21 3 Interference in Resonant Tunneling through a Single-Electron Transistor SVEN HEEMEYER, JÖRN GÖRES, DAVID GOLDHABER-GORDON, XIAO-GANG WEN, *MIT* We calculate the tunneling current through a quantum dot in a situation where two tunneling paths are available, namely a direct coupling between the leads and tunneling through a single resonant level of the dot. The calculation is carried out to all orders in the tunneling Hamiltonian. Interference between the two tunneling paths leads to asymmetric line shapes of the Fano type. The asymmetry is reduced as a phase shift between the paths is introduced or coherence is destroyed. We discuss the application of our results to recent experiments on single-electron transistors.

13:51

LC21 4 Response of a Quantum Dot in the Kondo Regime to a Pulsed Gate Voltage PETER NORDLANDER, *Rice University* MICHAEL PUSTILNIK, *Ben Gurion University* YIGAL MEIR, *Ben Gurion University* NED S. WINGREEN, *NEC Research Institute* DAVID C. LANGRETH, *Rutgers University** Using a time-dependent Anderson Hamiltonian and the NCA, we calculate the transient response of the current through a quantum dot when the level is subject to a abrupt shift. When the level is moved suddenly into the Kondo regime, the increase of the current follows the growth of the Kondo resonance in real time. Full formation of the resonance requires a time proportional to $1/T_K$ (or $1/T$ at temperatures higher than the Kondo temperature T_K). Using the Kondo Hamiltonian and Abrikosov's pseudofermion method we elucidate how the Kondo resonance develops in time. The suppression of the Kondo resonance at intermediate times is equivalent to the damping of a Kondo resonance in equilibrium caused by a finite temperature. An analytical relation between time and effective temperature is derived. An experiment for probing the dynamics of the Kondo effect is suggested.

LC21 5 AC Kondo Transport through Quantum Dots ROSA LOPEZ, RAMON AGUADO, GLORIA PLATERO, *Instituto de Ciencia de Materiales de Madrid (CSIC)* CARLOS TEJEDOR, *Departamento de Teoria de la Materia Condensada, Universidad Autonoma de Madrid)* It has been predicted and recently observed experimentally[1] that the transport at low temperatures through a quantum dot (QD) coupled by tunneling barriers to two leads containing Fermi liquids is governed by a Kondo-like singularity existing in the quasiparticle density of states (DOS) at the Fermi level ϵ_F of the leads. We have generalized the Friedel-Langreth sum rule to the case with AC potentials[2]. We study the photoassisted transport through QD taking especial care in the fulfillment of this generalized rule. New features are found in the transport properties due to the AC potentials. The effect of the AC potential on both the quantum dot density of states and the linear conductance shows the importance of using a theory which describes intradot finite interaction and nonperturbative effects[3]. In conclusion, our model considers, for the first time, finite U as well as charge conservation through the extension of the FL sum rule.

LC21 6 Fingerprints of the Kondo effect in optics of quantum dots MICHAEL PUSTILNIK, *Danish Institute of Fundamental Metrology, Building 307, Anker Engelunds Vej 1, DK-2800 Lyngby, Denmark* KONSTANTIN KIKOIN, YSHAI AVISHAI, *Department of Physics, Ben-Gurion University, Beer-Sheva 84105,*

Israel Semiconductor quantum dot coupled to the metallic leads is modeled by the generalized Anderson model, which allows for the particle and hole excitations of the impurity and bound electron-hole pairs (excitons). Special attention is paid to the regime when the dot is occupied by even number of electrons. In this case neither the ground state, nor the low-energy excitations of the system are influenced by the Kondo effect. Nevertheless, the Kondo-type final state interaction leads to emergence of novel midgap excitonic states, which appear as additional peaks in the optical absorption/emission spectra.

14:27

LC21 7 The Anderson impurity model realised in a quantum dot J. SCHMID, J. WEIS, K. VON KLITZING, K. EBERL, *Max-Planck-Institut für Festkörperforschung, Stuttgart, Germany** We study quantum dots in the regime of strong tunnel coupling to the leads. The well-known Coulomb blockade is observed, but in addition to this, we observe resonances within certain Coulomb blockade regimes that qualitatively agree with the Kondo resonances predicted for the Anderson impurity model. However, we also observe structures within Coulomb blockade regimes that are not described by this model, and attribute them to a more complicated excitation spectrum of our dots.

14:39

LC21 8 Spin and Charge Persistent Currents in a Kondo Ring HANS-PETER ECKLE,* *Department of Physics, University of Jyväskylä, Finland* HENRIK JOHANNESSON, *Institute of Theoretical Physics, Chalmers University of Technology and Göteborg University, Sweden* Persistent charge and spin currents in mesoscopic metallic rings have been an active field of research over the last years, both in experiments and theory. Here we focus on the influence of a magnetic impurity on the persistent currents. We consider a one-dimensional Kondo model on a ring of circumference L, with twisted boundary conditions on the electron wave function representing the magnetic flux ϕ threading the ring. The model is studied by a finite-size Bethe-Ansatz analysis, from which the properties of the spin and charge currents are obtained.

15:03

LC21 10 1D transport of an interacting electron pair in an electric field FRANCISCO CLARO, *P.Universidad Catolica de Chile, Santiago* JUAN FRANCISCO WEISZ, *CRICYT, Mendoza, Argentina* SERGIO CURILEF, *Universidad Catolica del Norte, Antofagasta, Chile* Transport takes place in the presence of an applied external field. We have studied the motion of a pair of interacting electrons in the presence of a weak external electric field in one dimension. We present analytic as well as numerical evidence that the interaction decreases the mobility of the center of mass in the ordered case, with a stronger effect if the potential is long range (Coulomb) compared to the contact (Hubbard) potential model. Results on the case with disorder will also be presented and discussed. Supported in part by FONDECYT, grant 1960417

15:15

LC21 11 Interacting Electrons in One Dimension with a Changing Electrostatic Potential SEBASTIAN EGGERT, *Chalmers and Göteborg University, Sweden* STEFAN ROMMER, *University of California, Irvine* We consider interacting electrons in one dimension with a changing electrostatic potential along the wire (i.e. a changing filling fraction). The correlation functions of the electrons are calculated in the limit of an extremely abrupt change. We believe that the results are relevant to conductivity experiments in a number of quasi one dimensional systems.

15:27

LC21 12 Transport properties of a two-channel quantum wire OLEG STARYKH, *Yale University* DMITRII MASLOV, *University of Florida* We consider transport properties of a two-channel quantum wire. Interaction between electrons give rise to intersubband Coooper scattering processes (also known as intersubband pair tunneling), in which a pair of electrons with opposite momenta in one subband is transfered to a similar state in the other. We show that such scattering may become relevant even for repulsive electron-electron interaction, opening a charge gap in a relative charge density sector and, simultaneously, opening spin gaps in spin sectors of each of the subbands. When this occurs, the tunneling density of states exibits a gap Δ, whose value is determined by the biggest of charge/spin gaps. Despite single-particle density of states being zero for energies less than Δ, the conductance of such a wire remains at its universal value $4e^2/h$.

SESSION LC22: WIDE BANDGAP SEMICONDUCTORS V: OPTICAL PROPERTIES

Tuesday afternoon, 23 March 1999

13:15

LC22 1 Optical Properties of GaN Pyramids K.C. ZENG, J.Y. LIN, H.X. JIANG, *Department of Physics, Kansas State University* WEI YANG, *Honeywell Technology Center* Picosecond time-resolved photoluminescence (PL) spectroscopy has been used to investigate the optical properties of GaN pyramids overgrown on hexagonal-patterned GaN(0001) epilayers on sapphire and silicon substrates with AlN buffer layers. We found that (i) the release of the biaxial compressive strain in GaN pyramids on GaN/AlN/sapphire substrate led to a 7 meV redshift of the spectral peak position with respect to the strained GaN epilayer grown under identical conditions; (ii) in the GaN pyramids on GaN/AlN/sapphire substrate, strong band-to-band transitions with much narrower linewidths than those in the GaN epilayer have been observed, indicating the improved crystalline quality of the overgrown pyramids; (iii) PL spectra taken from different parts of the pyramids revealed that the top of the pyramid had the highest crystalline quality; and (iv) the presence of strong band-to-impurity transitions in the pyramids, were primarily due to the

incorporation of the oxygen and silicon impurities from the SiO_2 mask. Properties of optically pumped lasing from these pyramids will also be discussed.

13:27

LC22 2 Time-resolved photoluminescence studies of single as-growth GaN hexagons by selective area growth hydride vapor phase epitaxy GABRIELA E. BUNEA, W.D. HERZOG, T.D. MOUSTAKAS, M.S. ÜNLÜ, B.B. GOLDBERG, *Departments of Physics, Electrical and Computer Engineering and Photonics Center, Boston University, Boston, MA, 02215* R. SINGH, F.P. DABKOWSKI, *Polaroid Corporation, Norwood, MA, 020602* Selective area growth of GaN has attracted considerable attention recently as a method for reducing the high threading dislocation density which has limited the device performance in the nitride systems. We report time-resolved photoluminescence (TRPL) studies on single as-grown GaN hexagons formed by selective area growth hydride vapor phase epitaxy (SAG-HVPE). When optically pumped these samples exhibit stimulated emission. At room temperature the PL signal exhibits several UV peaks decaying exponentially with time constants between 420-552 ps. A yellow luminescence signal is observed with a decay time constant of 1.63 ns consistent with the saturation of recombination centers at high excitation power. Detailed TRPL measurements as a function of temperature and excitation power is in progress to identify the various recombination mechanisms in strain-free GaN hexagons.

13:39

LC22 3 Time Resolved Spectroscopy of InGaN FREDERICK LONG, *Rutgers Univesity* MILAN POPHRISTIC, *Rutgers University* CHUONG TRAN, ROBERT KARLICEK, IAN FERGUSON, *EMCORE Corporation* We have used time-resolved fluorescence to investigate films, multiple quantum wells, and light-emitting diodes of InGaN. The photoluminescence decays not single exponential but are well-described by stretched exponentials. The stretched exponential kinetics are consistent with significant disorder in the material. We attribute the disorder to spatial fluctuations of the local indium concentration. An InGaN film exhibited nearly single exponential behavior at room temperature, the stretching parameter was between 0.9 and 1.05 at room temperature. The stretching parameter was observed to significantly decrease with temperature. The photoluminescence kinetics from a bright LED had a stretch parameter of 0.59. A series of InGaN/GaN multiple quantum wells with the same average indium concentration but varying degrees of indium phase segregation were also investigated. The local indium concentration fluctuations appear to have a major influence on the photoluminescence of InGaN.

13:51

LC22 4 First-principles calculation of VIS/UV optical absorption in GaN and AlN including the electron-hole interaction LORIN X. BENEDICT, ERIC L. SHIRLEY, *Optical Technology Division, NIST* We present calculations of $\epsilon_2(\omega)$ including the electron-hole interaction for wurtzite and zincblende phases of GaN and AlN. Comparison to reflectivity and ellipsometry results allows both an evaluation of the theory and an appraisal of different experiments. Among the topics to be discussed are the polarization dependence of the optical constants of the wurtzite phases, and the underlying character of prominent spectral features.

14:03

LC22 5 Multiphoton Excitation Microspectroscopy of Photoluminescence in GaN Films K. BURAK UCER, Y.C. ZHANG, R.T. WILLIAMS, *Wake Forest University, Department of Physics, Winston-Salem, NC 27109* Photoluminescence of GaN films prepared by MBE[1] and MOVPE[2] methods on sapphire/AlN substrates has been excited by 2- and 3- photon interband absorption of red or infrared sub-picosecond pulses. With 1.4 NA optics, the luminescence response has been spatially resolved to 200 nm laterally and about 700 nm axially (normal to the film interfaces). The spectral and spatial distribution of photoluminescence response complements studies made by cathodoluminescence[3]. Acknowledgment: Research supported by NSF grant DMR-9732023.

LC22 6 Femtosecond Coherent and Incoherent Spectroscopies on GaN epilayers* Y. D. JHO, *Department of Physics, Seoul National University, Seoul 151-742, Korea* D. S. KIM, *Department of Physics, Seoul Nationa University, Seoul 151-742, Korea* C. J. STANTON, *Department of Physics, University of Florida, Gainsville, Florida 32611* We have performed femtosecond pump-probe (P-P) simultaneously with the time-integrated (TI)-FWM and spectrally resolved (SR)-FWM experiments on high quality GaN epilayers in the high energy region of the tuning (700nm 716 nm) was used. The line widths of excitons in our sample are about 2.5 meV as revealed in the SR-FWM. P-P experiments are done with the combined use of a differential amplifier for reducing the laser noise. Some notable results are as follows. (1) Clear A-B exciton beats are found in both P-P and FWM experiments near the excitonic resonance. But the negative delay signal persists much longer for P-P compared to FWM, especially at resonant excitation condition. As we go away from the resonance rise time of P-P becomes same as that of FWM. (2) In P-P experiments at 11K, we see an osillatory behavior not from the A-B exciton beats but possibly from the interferenc between real and virtual signal slightly below the gap. (3) From the wavelength dependence at 175K in P-P, we see the rapid decrease emission rate of acoustic phonons.

14:27

LC22 7 Theory of Ultrafast Coherent and Incoherent Optical Spectroscopy in GaN J. A. KENROW, C. J. STANTON, K. EL SAYED, *Department of Physics, University of Florida, Gainesville* Y. D. JHO, D. S. KIM, *Department of Physics, Seoul National University, Korea* GaN-based semiconductors have recently attracted a great deal of interest resulting from their use in blue/UV LEDs and lasers. In this talk, we discuss the ultrafast optical response of bulk GaN to gain insight into the coherent and incoherent carrier dynamics. We calculate the femtosecond response of both pump-probe and four wave mixing experiments. The calculations are performed for reflection as well as transmission geometries. Our theory is based on the six band semiconductor Bloch equations at the Hartree-Fock level. A phenomenological relaxation mechanism is included. Differences between the respective reflection and transmission spectra are discussed and compared to recent experiments. We also discuss the role of contributions from intra-band versus inter-band transitions to the com-

puted pump-probe and four wave mixing lineshapes. This work was supported by the National Science Foundation through grant DMR 9520191.

14:39

LC22 8 Excitation wavelength dependence of stimulated emission from AlGaN epilayers B. D. LITTLE, *Oklahoma State University* T. J. SCHMIDT, *Oklahoma State University* S. BIDNYK, *Oklahoma State University* Y. H. CHO, *Oklahoma State University* G. H. PARK, *Oklahoma State University* J. J. SONG, *Oklahoma State University* WEI YANG, *Honeywell Technology Center* The characteristics of stimulated emission (SE) from AlGaN epilayers have been studied as a function of excitation wavelength at 10 K and room temperature. Samples used in this study were metal-organic chemical vapor deposition grown AlGaN layers with varying aluminum concentrations. The SE characteristics were monitored as the excitation wavelength was varied across the fundamental band edge of the AlGaN films using a tunable UV laser excitation source. The effect of tuning the excitation wavelength across the near band edge region on the emission spectra and SE threshold of the samples will be presented. The observed high excitation density behavior will be explained in conjunction with results from photoluminescence (PL), PL excitation, and time-resolved PL experiments. The results of this study will be compared with those obtained from high quality GaN and InGaN thin films of comparable alloy composition.

14:51

LC22 9 Observation of longitudinal laser modes in optically pumped GaN hexagons grown by hydride vapor phase epitaxy W.D. HERZOG, G.E. BUNEA, T.D. MOUSTAKAS, B.B. GOLDBERG, M.S. ÜNLÜ, *Boston University Departments of Physics, Electrical and Computer Engineering, and Photonics Center* R. SINGH, F.P. DABKOWSKI, *Laser Diode Manufacturing and Development, Polaroid Corporation* Reduction of threading dislocations in epitaxial lateral overgrowth GaN has recently resulted in renewed interest in the hydride vapor phase epitaxy (HVPE) method. Individual hexagons are formed by selective area growth (SAG) HVPE on patterned sapphire substrates. We have recently demonstrated the first stimulated emission from an individual SAG-HVPE hexagon.[1] The hexagons exhibit smooth sidewalls and are typically less than 100 μm in diameter and have a height of less than 50 μm. We report laser emission under optical excitation in various illumination configurations. The laser emission from optical pumping of a hexagon sidewall ($<$ 50 μm cavity formed by top and bottom surfaces) exhibits longitudinal modes consistent with the physical dimensions. Temperature dependence of photoluminescence and stimulated emission from room temperature to 77 K will be discussed.

LC22 10 Novel technique for evaluation of optical confinement in (In, Al) GaN heterostructures through spatially and spectrally resolved edge-emitted stimulated emission. SERGIY BIDNYK, *Oklahoma State University* T. J. SCHMIDT, *Oklahoma State University* J. J. SONG, *Oklahoma State University* We present an experimental study of the effects of increasing optical confinement on the mode structure and carrier competition of stimulated emission (SE) and lasing in (In, Al) GaN heterostructures. The edge-emitted near-field pattern of SE/lasing was imaged and spectrally resolved using a high-magnification optical assembly in conjunction with a sub-micron resolution positioning system. SE/lasing spectra were found to be strongly dependent on the position of collection optics relative to the active region. Spectral narrowing of the emission with increasing amplification path length was measured and compared with that obtained in variable stripe gain experiments. The information on the degree of optical confinement and interface roughness has been extracted through the analysis of spatially resolved high-excitation density emission spectra. We demonstrate that both the thickness of the active layer and near-band edge dispersion of the refractive index significantly affect the degree of optical confinement and emission spectra as well as the SE/lasing threshold. The implications of this study on the design of GaN-based laser diodes will be discussed.

SESSION LC23: LASER PROCESSING II: MECHANISMS AND MATRIX EFFECTS

LC23 1 A Microscopic View of Laser Ablation.

BARBARA J. GARRISON, *Department of Chemistry, Penn State, University Park, PA 16802*

A breathing sphere model has been developed for molecular dynamics simulations of laser ablation. The novel feature of this model is an approximate representation of the internal motion which permits a significant expansion of the time and length scales of the model yet still allows one to reproduce a realistic rate of the vibrational relaxation of excited molecules. Highlights of the model will be discussed as well as predictions that might be amenable for experimental verification.

13:51

LC23 2 Modeling and computer simulation of pulsed laser induced ablation SEBASTIANO TOSTO, *ENEA Casaccia, via Anguillarese 301, 00060 Roma, Italy* The paper introduces s 3D analytical model to calculate the ablation rate induced by a laser pulse on a semi-infinite slab of material of finite thickness. The model concerns first the thermal field induced by irradiation in order that the ablation process fulfil some prefixed boundary conditions, then the pulse fluence is calculated by consequence through the energy conservation. Some examples of computer simulation are presented to show the outputs of the model, in particular as concerns the correlation between shape of the ablated zone and space/time profile of the pulse. The results show that the present model enables to describe a variety of ablation processes like surface etching, cleaning and hole drilling.

14:03

LC23 3 Mechanisms of Infrared Laser Desorption and Ionization M. PAPANTONAKIS, M. BALTZ-KNORR, D. R. ERMER, R. F. HAGLUND JR., *Department of Physics and Astronomy and W. M. Keck Foundation Free Electron Laser Center, Vanderbilt University, Nashville, TN 37235* Infrared Matrix Assisted Laser Desorption/Ionization (IR-MALDI) has emerged in the past decade as a leading tool in the mass spectrometric identification and characterization of large molecules. Despite the many successes of MALDI, underlying mechanisms of the IR desorption/ionization process are not well understood. We have used a tunable, picosecond, free electron laser to target specific absorption modes of model infrared matriced to elucidate the desorption and ionization mechanisms. We observe that irradiation with wavelengths at the peak of the bulk absorption does not provide the most efficient MALDI signals, but that the optimal wavelengths for the lowest desorption/ionization thresholds are blue shifted from the absorption peaks. We will present several alternative models for the energy conversion processes which lead to IR-laser-induced desorption and ionization. This work was supported by the Medical Free-Electron Laser Program administered by the Office of Naval Research, under contract N-00014-94-1-1023.

14:15

LC23 4 The Wavelength Dependence of Infrared MALDI in the 3 μm Region KERMIT MURRAY, *Emory University* JAY SHEFFER, *Emory University* STEVEN LAWSON, *Emory University* Matrix-assisted laser desorption/ionization (MALDI) is a widely used technique for molecular weight and structural analysis of large biological and synthetic polymers. We will describe investigations of the behavior of MALDI in the 3 μm region of the infrared using a tunable optical parametric oscillator (OPO) and a linear time-of-flight mass spectrometer. We have performed studies of the wavelength dependence of MALDI using the threshold laser fluence for creation of protonated biomolecules as a measure of performance. In the case of carboxylic acid matrix compounds, ions are most readily created in the region of free OH stretch between 2.8 and 2.9 μm rather than in the region of hydrogen bonded OH absorption between 3 and 4 μm. We take this to be an indication of the creation of free molecules during the desorption process that continue to absorb photons during the 5 ns laser pulse. Trace water may also contribute to 2.9 μm absorption. We will report on several wavelength studies for crystalline matrix compounds as well as frozen solvents and liquids.

14:27

LC23 5 Infrared Laser Mass Spectrometry of Biomolecules in Liquid Matrices* MICHELLE BALTZ-KNORR, MICHAEL R. PAPNTONAKIS, DAVID R. ERMER, RICHARD F. HAGLUND JR., RICHARD M. CAPRIOLI, MARKUS STOECKLI, *Vanderbilt University* Matrix assisted laser desorption/ionization mass spectrometry in the infrared (IR-MALDI-MS) is an important analytical technique for identifying biomolecules. The use of vibrational excitation of specific absorption modes (e.g., O-H or C=O stretching vibrations) rather than electronic excitation, as in UV-MALDI, greatly expands the choice of possible matrices. Some of the most interesting applications of IR MALDI arise from the possibility of using liquid matrices, such as glycerol and water. We have carried out MALDI experiments using a tunable infrared free-electron laser, operating in the 2-9 μ m wavelength regime, to study model biomolecules in liquid matrices. Tuning the desorption laser to specific vibrational modes of the matrix yields better mass resolution and fewer adducts. Lower energy per unit volume is needed for IR desorption and ionization, thus limiting the possible damage to fragile biomolecules.

14:39

LC23 6 Imaging of Vapor Plumes Produced by Matrix Assisted Laser Desorption: A New Sharpening Effect A. A. PURETZKY, D. B. GEOHEGAN, G. B. HURST, M. V. BUCHANAN, *Oak Ridge National Laboratory* BORIS LUK'YANCHUK, *General Physics Institute, Moscow* Matrix assisted laser desorption ionization (MALDI) is now a well-established, commercial method for the laser desorption of intact large molecules for mass spectrometric analysis, and has recently been applied for film deposition of organic materials. In the process, a small concentration of heavy molecules are embedded in a light target material (matrix) and then desorbed to form a multicomponent plume. However, the fundamental mechanisms of matrix-assisted laser desorption, ionization and plume expansion are still not understood. We report the first gated LIF-imaging of both the matrix material and the heavy dye-tagged biomolecules during MALDI, and the development of a theoretical description of the 3D-expansion of the two component plume. The imaging shows that the heavy molecules propagate within a very narrow angular distribution compared to that of the matrix during MALDI. This distribution is observed to sharpen for extended time during propagation. A special solution of the gas dynamics equations was used to describe the 3D-dynamics of both the matrix (light) and embedded-molecule (heavy) plumes, and the observed sharpening effect. This work was supported by the Laboratory Directed Research and Development Program at ORNL.

14:51

LC23 7 Time- and Space-resolved Diagnosis of Laser Ablation Plasma Probed by Optical Transmittance TOMOJI KAWAI, WENJIE GUAN, TAKUYA MATSUMOTO, *ISIR-Sanken, Osaka University* Time- and space-resolved optical transmittance has been observed for the plasma generated by pulsed laser ablation of Ca, Sr, and Ba targets. A Gaussian distribution dynamic model including center-of-mass motion has been proposed to simulate the process of plasma expansion. The simulation shows that ratios of specific heat capacities at constant pressure and volume, γ, are 1.05, 1.10, and 1.15 for the ablation plasmas of Ca, Sr, and Ba, respectively. These values are much smaller than that of an ideal gas. It is ascribed to the non-equilibrium processes taking place in the plasma.

LC23 8 Room Temperature Ultraviolet Laser Emission from Self-Assembled ZnO Microcrystallite Thin Films Grown by Laser-MBE.

MASASHI KAWASAKI, *Dept. of Innovative and Engineered Materials,Tokyo Institute of Technology*

We report on the current status of ZnO thin film work directed towards ultraviolet laser diodes using pulsed laser deposition. The growth mode of ZnO thin film is regulated so that nanocrystals are assembled as a honeycomb structure

in a self-organized manner. Excitons in the nanocrystals can survive well above room temperature under high excitation, resulting in a stimulated emission with a low threshold caused by a collision process of excitons. The laser cavity is naturally formed by making use of grain boundaries between nanocrystals as mirrors. TE mode laser emission is observed from the edge of the films with showing six-fold symmetry in the azimuthal angle in the film plane. The band gap of ZnO can be tuned by alloying with MgO or CdO in a range of 3-4eV. Superlattices are readily made to show clear quantum size effect. The valence control into p-type conduction is the most critical materials challenge to realize ZnO ultraviolet laser diodes. LC23 9 Matrix Assisted Pulsed Laser Evaporation of High Quality Organic Thin Films DOUGLAS B. CHRISEY, *Naval Research Laboratory, Washington, D.C.* ALBERTO PIQUE, *Naval Research Laboratory, Washington, D.C.* JAMES FITZ-GERALD, *Naval Research Laboratory, Washington, D.C.* RAY C.Y. AUYEUNG, *Naval Research Laboratory, Washington, D.C.* ROBERT A. McGILL, *Naval Research Laboratory, Washington, D.C.* Matrix Assisted Pulsed Laser Evaporation (MAPLE) is an exciting new technique which has been used to extend the thin film deposition technique of Pulsed Laser Deposition (PLD) into the realm of fragile organic molecules and polymers. The MAPLE technique employs a simple variation of conventional PLD by utilizing a frozen dilute organic material and solvent matrix as the target. The low fluence laser pulse then preferentially interacts with the higly volatile solvent matrix as compared to the fragile organic. The organic molecule or polymer is then, through the collective collisions of the rapidly evaporating condensed solvent, gently desorbed from the target, transported, and deposited as a high quality and dense thin film without any loss in functionality or large scale fragmentation. We have demonstrated the advantages of the MAPLE technique with various organic molecules and polymers. This presentation will give an overview of the need for and the development of this technique and give specific examples of the organic materials deposited by MAPLE and their advantages in various gas sensing, electronic device and passivation applications areas.

15:51

LC23 10 Laser Induced Forward Transfer of Powders J.M. FITZ-GERALD, *Naval Research Laboratory* A. PIQU, *Naval Research Laboratory* R.C.Y. AUYEUNR, *Naval Research Laboratory* D.B. CHRISEY, *Naval Research Laboratory* R.A. McGILL, *Naval Research Laboratory* H.D. WU, *Naval Research Laboratory* P. WU, *Southern Oregon University* R. CHUNG, *Naval Research Laboratory* M. DUIGNAN, *Potomac Photonics* The field of powder technology has applications ranging from flat panel displays, rechargeable batteries, biomedical drug delivery, and ceramic cutting tools to name a few. Powder technology has received little attention in recent years with respect to combining commercially available particulate materials with existing deposition techniques. In this paper we present a novel technique using a pulsed excimer laser to selectively deposit particulate materials on solid substrates. This is in comparison to a process called laser induced forward transfer (LIFT), which has received added attention in recent years. The LIFT technique focuses around the interaction of lasers with solid metal films in order to generate a forward transfer of the molten metal onto a solid substrate. At NRL and Potomac Photonics we have modified this technique to transfer particulate materials such as dielectrics, ferroelectrics, ferrites, polymers and metals into complex structures ranging in size from 20 m to 2 mm wide onto a variety of substrates. A pulsed excimer laser (l = 248 nm) was used for these experiments. The laser was focused down to an average spot size of 25-30 mm with fluences ranging from 0.1 to 1.5 J/cm2 at repetition rates between 1-100 Hz. Laser transfer results of Al2O3, barium titanate (BTO) and yttrium iron garnet (YIG) deposited on silicon, glass, duroid and alumina will be presented along with device applications and future work. Characterization was performed by SEM, AFM, TEM, XRD and surface profilometry.

SESSION LC24: HIGH T_C BULK MATERIALS

LC24 1 Oxidation of Y-123 with Bromine* D. G. HINKS, O. CHMAISSEM, J. D. JORGENSEN, *Materials Science Division, Argonne National Laboratory* J. AKUJIEZE, C. SCOTT, *Chicago State University* Using thermogravimetic analysis and neutron powder diffraction, we show that Br intercalation processes that are claimed to induce superconductivity in non superconducting $YBa_2Cu_3O_6$ actually result in the decompostion of the Y-123 compound. Oxygen released during this reaction enters the Y-123 compound, increasing its oxygen content and inducing superconductivity, eventually leading to T_c near 90K. There is no evidence that Br enters the Y-123 compound.

LC24 3 Isotope Shift in $Y_1Ba_2Cu_{2.7}Fe_{0.3}O_y$ Samples* N. EL BOUDAKHANI, P. BOOLCHAND, *Department of Electrical Engineering, University of Cincinnati* K. CONDER, *ETH, Zurich, Switzerland* A. BUSSMANN-HOLDER, *MPI, Stuttgart, Germany* Titled superconductors synthesized at Ambient Pressures of Oxygen (APO) possess a T_c of about 35K. An additional sinter of such samples at High Pressures of Oxygen (HPO) increases[1] T_c to 86K and the shielding fraction to nearly -1/4π. The Fe local environments in HPO samples display a distribution that differs qualitatively from the one in APO samples. We have now exchanged oxygen ($O^{16} \rightarrow O^{18}$) in APO samples and find T_c to decrease by 3.5K (36.5 $\rightarrow$ 32.5K) and each of the three Raman mode frequencies (338 cm^{-1}, 481 cm^{-1}, 588 cm^{-1}) to fractionally redshift by 5.7 %. Parallel oxygen exchange on HPO samples also reveals an isotope shift (50.0K $\rightarrow$ 47.5K) in T_c, although the large depression in T_c of both the reference and exchanged samples from 86K has occurred due to the high-T used in oxygen exchange. The results underscore that Fe is not detrimental to HTSC and phonons certainly have a role in pairing of superconducting charge carriers.

LC24 4 Crystal Growth of the Ladder Compounds $La_{4+4n}Cu_{8+2n}O_{14+8n}$ (n=2,3) by Modified Slow Cooling Technique and Their Properties CHINNATHAMBI SEKAR, TAKAO WATANABE, AZUSA MATSUDA, *NTT Basic Research Laboratories, 3-1 Wakamiya, Morinosato, Atsugi-shi, Kanagawa 243-0198, Japan* We report the successful crystal growth of the 4-leg ladder compound $La_2Cu_2O_5$ (with sizes upto 0.2x3.5x0.2 mm^3) and, for the first time, 5-leg ladder compound $La_8Cu_7O_{19}$ (with sizes upto 0.3x1.4x0.2 mm^3) and their transport properties. Because liquidus lines for both La-225 and La-8719 have narrow ranges in temperature and composition, simple slow cooling is not sufficient to grow large size single crystals. We propose here a modified technique in which a flux(CuO) poor starting composition was used to gain enough supersaturation and also quenching from high temperature to a proper crystallization temperature was done to avoid the La-214 phase formation. Room temperature resistivity parallel to the ladder direction(//b) are estimated as $1.7x10^3$ ohm cm and 24.6 ohm cm for the as grown crystals of La-225 and La-8719 respectively. The resistivity decreases by three orders of magnitude upon hole doping using HIP furnace, but no transition from the semiconducting behavior was observed. Further decrease in the resistivity down to 8 mohm cm was observed for the HIPed La-225 crystals grown with an additive.

14:03

LC24 5 Magnetism and Supercoductivity in $Sr_2A(Ru_{1-x}Cu_x)O_6$ (A=Y, Ho) System* F.Z. CHIEN, D.C. LING, *Tamkang University* D.Y. CHEN, L.Y. LU, M.K. WU, *National Tsing Hua University* We have synthesized a series of Cu-doping $Sr_2A(Ru_{1-x}Cu_x)O_6$ compounds, with A = Y or Ho, and x < 0.2. We observed superconducting transition, by both resistive and magnetic measurements, in samples with the doping level x > 0.04. Detailed structural analyses show single phase double perovskite structure in all the samples studied. In addition, magnetic orders occur at a temperature close to that of the superconducting transition, are also present in the samples. There is additional magnetic order at about 10K in those samples contain Ho. Detailed magnetic susceptibility measurements in high magnetic fields suggest the 10K transition is ferromagnetic in nature, presumably due to Ho order.

14:15

LC24 6 Synthesis of 75K Superconductor Sr3Cu2O6-x at High Pressure YANHUI WANG, *LDEO,Columbia Univ, Palisades, NY 10964* WALKER DAVID, *LDEO,Columbia Univ, Palisades, NY 10964* SCOTT BRUCE, *IBM TJ Watson Res Ctr, Yorktown Heights, NY 10598* Superconductivity (SC) in the Sr-Cu-O system has long been debated. Although the $Sr_{n+1}Cu_nO_{2n+2-x}$ series was proposed superconductive, strong evidence shows that the n=1 member, Sr_2CuO_{4-x}, is in fact not superconducting. Moreover, Sr-Cu-O system is extremely H_2O- and CO_2-sensitive, and Cl-contamination was observed when using $KClO_3$ as oxidizer in the high-pressure(H-P) synthesis. Because samples obtained at H-P typically show small Meissner fractions (~ 10Sr-Cu-Cl-O systems, the source of ''Sr-Cu-O'' SC was totally unclear. In this study, we use SrO_2 as the oxidizer. Precursor preparation and handling were done with extreme caution to avoid CO_2. H-P working conditions are varied from 60 to 100 kbar. We found: (1) in Sr-Cu-O, at least two superconductors with Tc=75K and 96K exist; (2) at 60kbar, members of the target series tend to intergrow together. The non-superconducting Sr_2CuO_{4-x} always appears as main phase in the reaction products; (3) reaction kinetics changes with pressure. At 100kbar/1000°C, n=2 member $Sr_3Cu_2O_{6-x}$ can be formed w/o occurence of Sr_2CuO_{4-x}. Bulk SC(> 60%) of Tc=75K was thus observed. It is a tetragonal phase of a=3.88A, c=20.80A whose composition was measured by electron microprobe. The 96K superconductor is still under investigation.

14:27

LC24 7 Superconducting $PrBa_2Cu_3O_7$ (Pr123-7): failure of attempts to restore a cuprate-plane model*. HOWARD A. BLACKSTEAD, *University of Notre Dame* JOHN D. DOW, *Arizona State University* — With most of the many confirmations of superconductivity in Pr123-7 come proposals for how to restore the cuprate-plane model of superconductivity in the face of the facts that Pr_{Ba} (Pr-on-a-Ba-site) destroys superconductivity, but Pr_{Pr} does not — although the two sites are symmetrically placed with respect to the cuprate-plane half-way between them. Claims that (i) Ba occupies Pr sites in significant numbers, or that (ii) Pr is Pr^{+4} on either site, or that (iii) hybridization is important are ruled out and shown to be invalid. *Supported by ARO and ONR.

14:39

LC24 8 Growth and Properties of Corrosion-Resistant 123 Crystals* E. E. JUDGE, J. T. MARKERT, *The University of Texas at Austin* We have found conditions for crystal growth of cation-substituted $YBa_2Cu_3O_{7-\delta}$ (YBCO). The target composition is $Y_{0.6}Ca_{0.4}Ba_{1.6}La_{0.4}Cu_3O_{7-\delta}$; this composition is significantly less reactive than YBCO. For example, YBCO degrades quickly upon exposure to moisture, whereas $Y_{0.6}Ca_{0.4}Ba_{1.6}La_{0.4}Cu_3O_{7-\delta}$ exhibits stability after 30 days in water*. Reduced reactivity in single crystal specimens will be useful for surface and interface research. We modified the flux-based crystal growth

method by exploring various melt compositions and finding appropriate soak temperatures (~ 1020°C) and cooling rates (~ 4°C/hr). For example, for crystals from a $Y_{0.6}Ca_{0.4}Ba_{3.6}La_{0.4}Cu_{10}O_x$ melt, energy dispersive spectroscopy measurements indicate a stoichiometry of approximately $Y_{0.78}Ca_{0.22}Ba_{1.45}La_{0.55}Cu_3O_{7-\delta}$. Thus about half of the desired Ca substitution was achieved, and an apparent excess La substitution occurred. Single crystals with other stoichiometries were obtained by varying the melt composition. X-ray diffraction, SQUID magnetometry, and oxygen annealing data for the single crystals as well as polycrystalline specimens are also presented.

LC24 9 Easy method to fabricate high Jc superconductor* WEI LI, DEZHI WANG, ZHIFENG REN, JUI H. WANG, *State University of New York at Buffalo* M. PARANTHAMAN, D. T. VEREBELYI, D. K. CHRISTEN, *Solid Division, Oak Ridge National Laboratory* The simple, easy, low-cost, and scalable thermal spray was used to make the precursor films, followed by annealing to fabricate high-Tc superconducting films. First the water solution containing Tl, Pb, Sr, Ba, Ca, Cu nitrates stoichiometrically was sprayed to the LaAlO3 substrates at 400-500 degrees, then the spray-deposited amorphous films were crystallized at 870 degree in air by annealing them inside a silver package with two half circle unfired pellets. X-ray diffraction (XRD) showed that the films consist of mainly c-axis aligned (Tl,Pb)-1223 phase with a small amount of (Tl,Pb)-1212 phase. X-ray phy scan revealed epitaxial film growth. Four-probe transport measurement showed superconducting transition temperatures (Tc's) in the range of 106-109 K, and a critical current (Ic) on the whole cross section of the sample (4 mm wide and 1.2m thick) at 77K and zero field is 51 A, corresponding to a critical current density (Jc) of 1,000,000A/cm2.

15:03

LC24 10 Effect of Ba site Substitution and Charge Compensation on the Superconductivity of $YBa_2Cu_3O_{7-\delta}$ JOHN ULANDAY, JONATHAN OBIEN, JAYARAM BETANABHATLA, *University of Nebraska** Earlier studies have indicated that Pr, substituted at the Y-site, partially substitutes for Ba, and this, to some degree, is responsible for the depression of T_c. In order to investigate this aspect we have studied materials with the composition $Y_{1-x}Ca_xBa_{2-x}(Pr/La)_xCu_3O_{7-\delta}$. To compensate for the substitution of a trivalent ion at the Ba-site, calcium was substituted at the Y-site. We have studied the structure, oxygen stoichiometry, resistivity, and magnetization properties of substituted materials in the normal as well as superconducting states. We have also studied the dependence of these properties on the processing conditions. Our measurements reveal a monotonous suppression of T_c with the increasing concentration of Pr, materials with x(Pr) > 0.6 are not superconducting. On the other hand with La substitution T_c remained almost constant. In the normal state the susceptibility of Pr substituted materials was found to follow Curie-Weiss relation. * Supported by DOE under Grant FG01-90ER45427 through the Midwest Superconductivity Consortium.

LC25 1 Magnetic Anisotropy and Hysteresis of the Zero Bias Conductance Peak in YBCO/Pb tunnel junctions. L.H. GREENE,*M. APRILI,†E. PARAOANU, *Physics Dept., Univ. of Illinois at Urbana*‡ J.A. SAULS, *Physics Dept., Northwestern Univ.*§ The effect of applied magnetic field on the Zero Bias Conductance Peak (ZBCP), observed in the in-plane tunneling spectra of $YBa_2Cu_3O_7$/Pb tunnel junctions, is reported.[1] The integrated weight obtained from the tunneling density of states (DoS) is conserved with increasing magnetic field, and the magnitude of the field-induced splitting depends upon the orientation of the applied field within the ab-plane of the $YBa_2Cu_3O_7$, as expected for the ZBCP being a surface-induced Andreev bound state (ABS) of the d-wave order parameter.[2] The splitting of the ZBCP exhibits hysteresis with increasing and decreasing applied magnetic field. We discuss this result and a possible interpretation in terms of surface and bulk pinning of vortices and their effect on the surface screening current and Doppler shift of the ABS.

LC25 2 Effects of disorder and doping on the Andreev Bound State in YBCO.* E. PARAOANU,† *Dept. of Physics, University of Illinois at Urbana-Champaign* M. APRILI,‡ *CSNSM, Orsay, France* M. COVINGTON,§ *NIST, Boulder, Colorado* L.H. GREENE,‖ *Dept. of Physics, University of Illinois at Urbana-Champaign* Effects of disorder on the in-plane tunneling density of states (DOS) of YBCO are investigated by planar tunneling spectroscopy. Disorder is induced via substituting Ni and Zn for Cu in the CuO_2 planes. The height of the zero bias conductance peak (ZBCP) is reduced with increased disorder and it disappears as the dirty limit is approached[1]. We show this is a measure of the quasiparticle scattering rate below T_c, consistent with previous work on Pr-doping[2] and ion irradiation[3], and a theoretical model[4]. These observations, together with the temperature[5] and magnetic field[6] dependences, show the ZBCP is an Andreev Bound state of the d-wave superconductor. This work was done in collaboration with M. Fogelström and J. A. Sauls.

LC25 3 Quasiparticle Tunneling and Andreev Reflection Study of the Pseudogap in Underdoped $La_{2-x}Sr_xCuO_4$ and $YBa_2Cu_3O_{6+x}$* J. Y.T. WEI, C.-T. CHEN, C.-C. FU, N.-C. YEH, *Department of Physics, California Institute of Technology, Pasadena, CA 91125* R.P. VASQUEZ, *Center for Space Microelectronics Technology, Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA 91109* Scanning tunneling and point-contact spectroscopy measurements are performed on epitaxial-film and single-cristal samples of underdoped $La_{2-x}Sr_xCuO_4$ and $YBa_2Cu_3O_{6+x}$ to study the pseudogap characteristics as a function of temperature. The measurements are made between 4.2K and 100K, to understand how the size, symmetry, and character of the superconducting order parameter evolve through the critical temperature T_c and below the pseudogap temperature T*. In particular, the $2\Delta_0/k_BT_c$ and $2\Delta^*/k_BT^*$ ratios are determined, where Δ_0 and Δ^* are the respective gap-maxima. The occurrence of a zero-bias peak in the tunneling conductance is interpreted as a signature of d-wave pairing symmetry, while an Andreev-reflection behavior in the point-contact spectra is understood as a direct manifestation of the particle-particle nature of the pseudogap. The results are discussed in terms of recent theoretical models, including pair-density fluctuations and Bose-Einstein condensation of pre-formed pairs.

LC25 4 Study of Zero Bias Conductance Peak observed in superconductor-metal tunneling spectroscopy SAION SINHA, *University of North Carolina , Chapel Hill, NC-27599* KWOK-WAI NG, *University of Kentucky, Lexington, KY-40506* Zero bias conductance peaks in high Tc superconductor tunnel junctions have recently been widely studied both theoretically and experimentally. We will be presenting a detailed analysis of the Zero bias Conductance Peaks which we have observed in a normal metal to BSCCO tunneling spectroscopy studies. Pb, a s-wave superconductor (Tc = 7.2K and Hc = 0.08 T) and Ag a metal was used as the counter electrode and both temperature and magnetic field dependence was studied. The results will be discussed in the view of the contemporary d-wave theories. A large number of junctions with variable junction parameters were studied experimentally and the results highlight some differences with the theory. These will be elaborated further by some simulation studies based on a simplistic model.

14:03

LC25 5 Impurity-Induced Bound Excitations on the Surface of $Bi_2Sr_2CaCu_2O_8$ ALI YAZDANI, *University of Illinois* C. HOWALD, A. KAPITULNIK, *Stanford* C. P. LUTZ, D. M. EIGLER, *IBM Almaden* We have probed the effects of atomic-scale impurities on superconductivity in $Bi_2Sr_2CaCu_2O_8$ by performing spatially resolved tunneling spectroscopy with a scanning tunneling microscope operating in UHV and at low temperatures. Our measurements show that non-magnetic defects structures at the surface create spatially localized low-energy excitations in their immediate vicinity. The occurrence of these bound excitations for non-magnetic impurities is a predicted local signatures for a d-wave superconductor.[1] Our most intriguing observation is that these impurity-induced excitations can occur essentially in the middle of the superconducting gap, at the Fermi level. While this phenomena is predicted signature for impurities scattering in the unitary limit, it can also be understood considering Andreev scattering near extended impurities in a d-wave superconductor[2].

LC25 6 High Resolution Low Temperature Scanning Tunneling Spectroscopy on Vortex Cores and Crystal Defects in $Bi_2Sr_2CaCu_2O_{8+\delta}$* E.W. HUDSON, S.H. PAN, J.C. DAVIS,† *University of California, Berkeley* ANJAN GUPTA, K.-W. NG, *University of Kentucky* Tunneling spectroscopy was performed on *in situ* cleaved $Bi_2Sr_2CaCu_2O_{8+\delta}$ single crystals with a very low temperature scanning tunneling microscope. Rich spectral features and their spatial variations are observed. We will focus on the zero bias conductance features associated with crystal defects and magnetic vortices. Studies of spectral variations with distance from these vortex cores and defects will also be discussed.

LC25 7 Selfconsistent Domain-Wall Structure in Superconductors SAMI M. M. VIRTANEN, MARTTI M. SALOMAA, *Materials Physics Laboratory, Helsinki University of Technology, P.O. Box 2200 (Technical Physics), FIN-02015 Hut, Finland* We calculate the electronic excitation spectrum for domain walls in s-wave superconductors in the framework of the Bogoliubov-de Gennes theory. The computations are carried out fully self-consistently in order to obtain the spatial distribution of the pair potential as a function of temperature. At low temperatures, the pair potential steepens markedly in comparison to the Ginzburg-Landau regime and the discrete bound-state quasiparticle spectrum is reflected in the superconducting pair potential. We predict the tunneling conductance, to be measured with STM spectroscopy, from the elementary single-quasiparticle excitations. The STM spectroscopic response is related to details of the bound-state spectrum at low energies.

14:39

LC25 8 Electronic Structure of Multiply Quantized Vortices in Superconductors SAMI M. M. VIRTANEN, MARTTI M. SALOMAA, *Materials Physics Laboratory, Helsinki University of Technology, P.O. Box 2200 (Technical Physics), FIN-02015 HUT, FINLAND* Applying the method[1] based on the Bogoliubov-de Gennes equations, we determine the selfconsistent quasiparticle excitation spectrum for axisymmetric multiply quantized vortices (with m flux quanta) in s-wave superconductors. We find that there occur m branches of bound-state excitations as a function of the quantum number μ for the quasiparticle angular momentum. This spectral structure leads to an intriguing layered radial supercurrent distribution, displaying m extrema along the radial distance from the vortex axis. We compute the selfconsistent superconducting pair potential and vortex properties for m-tuple vortices as a function of temperature. We also predict the characteristic shape of the tunneling conductance for m-quantum vortices and relate it to the novel branched structure of the bound-state excitations. We challenge experimentalists to look for these fingerprints of multiply quantized vortices with the help of STM spectroscopy. [1] F. Gygi and M. Schlüter, Phys. Rev. B 43, 7609 (1991).

14:51
LC25 9 STM/S of BSCCO* WILLIAM E. PACKARD, *Arizona State University* JOHN D. DOW, *Arizona State University.* A new, low-temperature STM design will be presented, and features a compact STM immersible in liquid helium, using a molecular sieve to obtain UHV. This microscope has *in situ* cleavage and fast turn-around time. It permits both ordinary STM/S and cross-sectional measurements. Our STM/S measurements on BSCCO raise serious doubts about conventional interpretations in terms of cuprate-plane superconductivity: these assign the superconducting layer to the *third* layer down from the BiO surface layer, while the intervening layers apparently are transparent to electrons. We shall present our data together with an interpretation in terms of charge-reservoir superconductivity — and let the audience decide. **Supported by ARO and ONR*

15:03
LC25 10 Electronic Transport in Nb-InGaAs Tunnel Junctions[1] A.C. ABEYTA, I.V. ROSHCHIN, L.H. GREENE, *Dept. of Physics* T.S. YEOH, J.J. COLEMAN, *Dept. of Electrical and Computer Engineering; Univ. of Illinois at Urbana-Champaign* J.F. KLEM, *Sandia National Laboratory* Electronic transport measurements of high-transmittance superconductor/semiconductor junctions are presented. Transport properties of small (100-2500 μm^2) junctions of Nb on n^+ InGaAs are performed as a function of doping of the InGaAs from the low to the middle $10^{18} cm^{-3}$ range. N^+ InGaAs doped to the low $10^{19} cm^{-3}$ range, achieved by diffusion doping, are also being investigated. At the highest doping levels, a deviation from the standard Nb tunneling density of states is observed, which we analyze in terms of proximity effect and mesoscopic models. The effect of microwave irradiation and applied magnetic field on SNS and SN junctions, where S is Nb and N is InGaAs, will also be reported. [1]*Supported by DoE through MRL (DEFG02-91ER45439).*

15:15
LC25 11 Superconducting Proximity Effect in Superconductor/Semiconductor Lateral Structures I.V. ROSHCHIN, A.C. ABEYTA, L.H. GREENE, *Dept. of Physics, Univ. of Illinois at Urbana** T.A. TANZER,[†]P.W. BOHN, *Dept. of Chemistry, Univ. of Illinois at Urbana* W.L. MURPHY, G.C. SPALDING, *Illinois Wesleyan Univ.* J.F. KLEM, *Sandia National Lab*[‡] The proximity effect in superconductor-semiconductor interfaces is observed using Raman scattering[1] in a geometry where the signal is obtained from the InAs through a thin film of Nb (T_c=2.5-4K). Recently a theoretical model for this proximity effect was proposed.[2] In a new experiment we use a lateral geometry where the temperature dependent Raman spectra are obtained from bare InAs between Nb ($T_c \sim$ 9K) stripes. A finger-like structure consisting of 200nm Nb lines, spaced by the same distance, is fabricated on a (100)-n^+ InAs substrate ($10^{19} cm^{-3}$) using e-beam lithography. The LO phonon mode ($237 cm^{-1}$) and the plasmon-phonon coupled modes, L_- ($221 cm^{-1}$) and L_+ (position is carrier concentration dependent), are studied; the results are discussed in scope of the proximity effect. Effects of microwave irradiation on the electronic transport in both geometries are investigated.

SESSION LC26: GRAIN BOUNDARIES IN SUPERCONDUCTORS
Tuesday afternoon, 23 March 1999
Room 170W GWCC at 13:15
D.E. Oates, Massachusetts Institute of Technology, Lincoln Lab, presiding

13:15
LC26 1 Measurements and modeling of Bi-crystal Grain Boundaries at Microwave Frequencies* D.E. OATES, *MIT Lincoln Lab, Lexington MA 02420* Y.M. HABIB, *MIT, Cambridge, MA 02139* L.R. VALE, R.H. ONO, *NIST Boulder, CO 80303* M.S. DRESSELHAUS, G. DRESSELHAUS, *MIT, Cambridge, MA 02139* We present measurements and modeling of the microwave-frequency (rf) nonlinear effects in YBCO thin-film grain boundaries using a stripline-resonator technique that separates the characteristics of the grain boundary from the rest of the film. The measurements include the power-dependent impedance and second and third harmonic generation. The grain boundaries are fabricated on sapphire bicrystal substrates with misorientation angles varying from 2 to 24 degrees and on single-crystal sapphire substrates. Measurements of the dc I-V characteristics were also performed. The rf measurements are presented as a function of rf current (0.1 mA to 1 A) and temperature (6 to 80 K). Measurements have been made at 3 and 6 GHz. Grain-boundary angles of 10 and 24 degrees show Josephson-junction behavior in the rf measurements, but at angles of 5 degrees or less the impedance is indistinguishable from films grown on single-crystal substrates. Implications for the film power dependence and for passive microwave devices will be discussed.

13:27
LC26 2 Novel interference phenomena in tunneling from a normal metal into a *d*-wave superconductor containing a grain boundary.* QIAN WANG, CHIA-REN HU, *Department of Physics, Texas A&M University* We report a theoretical study of novel interference phenomena in the single-particle tunneling characteristics of an $NID_{x^2-y^2}I'D_{2xy}$ junction, where the $D_{x^2-y^2}I'D_{2xy}$ part represents a *d*-wave superconductor containing two grains of different crystal orientations and a grain boundary (or interface). It is probed by a normal electrode, N. *x* is the tunneling direction. In this system, when I is weak, an incoming electron from N can either Andreev-reflect from $D_{x^2-y^2}$, or, if its energy is near zero, first undergo a resonant tunneling into one of the midgap states[1] at the $D_{x^2-y^2}I'D_{2xy}$ interface, and then return back to the N side as a hole, effectively executing an Andreev reflection from D_{2xy}. These two paths of Andreev reflection can lead to a novel type of interference. Another type of interference occurs at energies above the gap in $D_{x^2-y^2}$, which is also between two paths of Andreev reflection, but not involving the midgap states. The latter can weakly exist in *s*-wave superconductors, but not the former.

13:39

LC26 3 Local single-particle tunneling characteristics between a normal metal and a *d*-wave superconductor near a grain boundary* HONGWEI ZHAO, CHIA-REN HU, *Department of Physics, Texas A&M University* A recent work by one of us (CRH)[1] has calculated the single-particle tunneling characteristics of an NIS junction where S is a *d*-wave superconductor containing two grains of different crystal orientations. The tunneling Hamiltonian approach was used. A zero-bias conductance peak was shown to occur due to the midgap states which exist at the interface between the two grains. That calculation invoked an average of the tunneling location over the whole two-grained sample. Here we report our extension of that work to *local* tunneling characteristics at various distances from the interface. Using the quasiclassical Green function method, we have first determined the *self-consistent* gap function for *arbitrary reflection coefficient* at the interface. We then calculated the local density of states, and the local tunneling characteristics. The results are compared with those obtained by directly solving the Bogoliubov-de Gennes equations for a constant gap function in each grain.

13:51

LC26 4 The Origin of Reduced Jc at Grain Boundaries in YBa2Cu3O7 JAMES BUBAN, *University of Illinois at Chicago* NIGEL BROWNING, *University of Illinois at Chicago* Grain boundaries (GBs) have long been known to drastically reduce the critical currents in high-Tc superconductors. The key to understanding the origin of this detrimental effect is to study the atomic structure of the boundary. In this study, asymmetric GBs in YBa2Cu3O7 are modeled using data form Z-contrast imaging in the scanning transmission electron microscope. Our structural models show intrinsic oxygen vacancies in the GB plane causing a depletion of charge carriers. This depletion of charge carriers increases as a function of the misorientation angle and produces a potential barrier to the flow of supercurrent. Considering this as a one-dimensional quantum potential barrier, the tunneling current across it should decrease with an exponential dependence on the barrier width. This dependence is in accordance with the widely reported experimental transport measurements from GBs in high-Tc superconductors. This model suggests that intrinsic oxygen vacancies are the source of the reduced Jc at GBs and impose an upper limit to transport that is independent of processing parameters.

14:03

LC26 5 Influence of Nanometer-scale Structures at Grain Boundaries of Bicrystalline $SrTiO_3$ Substrates and YBCO Thin Films on the Transport Properties of Grain Boundary Junctions* Q. D. JIANG, M. G. MEDICI,[†]M. DEZANETI,[‡]C. W. CHU, *Texas Center for Superconductivity, University of Houston, Houston, TX 77204-5932* Non-destructive scanning probe microscopy has been applied to reveal the nanometer-scale surface structures at grain boundaries of bicrystalline $SrTiO_3$ substrates and overlayer epitaxial YBCO thin films. YBCO films of various thicknesses were epitaxially grown by RF magnetron sputtering onto thermally annealed and well-characterized $SrTiO_3$ bicrystal substrates which exhibit respectively atomically sharp boundaries, regularly and irregularly faceted grooves at grain boundaries. The influnces of microstructures at the boundaries of substrates on the microstructures at boundaries of YBCO films, and consequently on the properties of bicrystal grain boundary Josephson junctions, are presented.

14:15

LC26 6 Conductance characteristics in $Bi_2Sr_2CaCu_2O_{8-\delta}$ based heteroestructures* PEDRO PRIETO, EVAL BACA, MARIA E. GOMEZ, VICTOR HOLGUIN, ANDRES SALINAS, *Departamento de Física Universidad del Valle A.A. 25360 Cali, Colombia* We have deposited $Bi_2Sr_2CaCu_2O_{8-\delta}$ /$Bi_2Sr_2YCu_2O_{8-\delta}$/$Bi_2Sr_2CaCu_2O_{8-\delta}$ heterostructures by an *in situ* dc-sputtering technique at high oxygen pressures on (001) $SrTiO_3$ substrates. The structural characteristics has been determined by x-ray diffraction, Rutherford backscattering and transmission electron microscopy that confirm the epitaxial growth of the heterostructures with very sharp interfaces. The critical temperatures for the bottom and top electrodes were above 85 K. Semiconductor-like $Bi_2Sr_2YCu_2O_{8-\delta}$ epitaxial films with thickness ranging between 5 to 12 nm were used as artificial barriers. Clear quasiparticle tunneling indicating a gap structure at about 35 mV, a zero bias anomaly as well as a linear behavior at high bias have been observed in the conductance curves. For thinner barriers a weak link type behavior was observed. An analysis of the I-V curves for these junctions has been made based on the resistively shunted Junction (RSJ) model.

14:27

LC26 7 Critical Current of YBCO Grain Boundaries in High Magnetic Field D.T. VEREBELYI, D.K. CHRISTEN, R. FEENSTRA, *Oak Ridge National Laboratory* C. PROUTEAU, *University of Birmingham* The applied magnetic field (H) dependence of critical current density (J_c) for YBCO single grain boundaries have been studied. Numerous [001] tilt boundaries with a range of misorientation angles have been investigated in detail. The weak-link character of the grain boundary causes J_c to exhibit dramatic hysteretic behavior in H. A prominent peak in J_c is found at a field (H_{peak}), with decreasing H, for all of the grain boundaries studied. H_{peak} varies exponentially with T and increases with decreasing T. In the case of small misorientation angles at low T, J_c of H_{peak} is significantly larger than the virgin, self-field J_c. Research cosponsored by the DOE Division of Materials Sciences, the DOE Office of Advanced Utility Concepts, under contract DE-AC05-96OR22464 with Lockheed Martin Energy Research Corp.

14:39

LC26 8 Critical Currents and the Ambegaokar-Baratoff to Ginsburg-Landau Crossover in Granular Superconductor* JOSE-LUIS CARDOSO, *Facultad de Cienciàs, UNAM, C.P. 04510, México D.F.* PEDRO PEREYRA, *Depto. de Ciencias Básicas, UAM-Azcapotzalco, C.P. 02200, México D.F.* A simple expression for the critical transport current, which describes rather well the Ambegaokar-Baratoff (A-B) to Ginsburg-Landau (G-L) crossover, is obtained from an elementary analysis of a Josephson junction subject to external magnetic fields within the Ginzburg-Landau theory. We show that the order parameter in the intergrain region depends crucially on the interplay of two characteristic

lengths: the superconducting coherence length $\xi \propto (1 - T/T_c)^{-1/2}$ and the junction-induced superconducting decoherence length $\zeta_q \propto (1 - T/T_c)^{-\alpha}$. New data for the critical transport current in granular YBCO samples are presented, and the A-B to G-L crossovers successfully described.

*Research partially supported by CONACyT México, Project No. 350-E9301

14:51

LC26 9 Symmetric and Non-symmetric Superconducting Grain-Boundaries: a Self-Consistent S- and D-wave study. JASON HOGAN-O'NEILL, *University of Bristol* ANDREW MARTIN, *University of Geneva* JAMES ANNETT, *University of Bristol* UNIVERSITY OF BRISTOL, THEORETICAL PHYSICS TEAM, Grain-boundaries are important weak-link junctions in high T_c superconductors. Previously the study of interfaces in superconductors has been confined to flat interfaces or 90^o twin boundaries, and have relied upon k-space calculations. Here we use a more realistic model, butting together two squares lattices at an angle of misorientation , θ. We find two general classes of boundary, symmetric and non-symmetric. For such systems we self-consistently solve the Bogoliubov-de Gennes equations using the Recursion Method for both s- and d-wave superconductors. Our real space method calculates how the superconducting order parameters, charge densities, and local densities of states are affected by the boundary. In a d-wave system we find an induced extended-s component at the boundary. By imposing phase differences in either order parameter across the boundary we present self-consistent profiles of current versus phase and find a sawtooth profile with a step at $+/-\pi$. This step can be attributed to a sudden filling-in of the energy gap at this phase difference. In the symmetric junction we do not find broken time reversal symmetry.

15:03

LC26 10 Noise in New $YBa_2Cu_3O_y45^o$ bi-epitaxial Josephson Junctions and dc SQUID* B.C. YAO, S.H. TSAI, C.C. CHI, M.K. WU, *Department of Physics and Materials Science Center, National Tsing Hua University, Hsinchu, Taiwan, R.O.C.* We have developed a new structure[1] of 45^o bi-epitaxial grain boundary junction, i.e. YBCO(780^{o}C)/YSZ and YBCO(780^{o}C)/YBCO (600^{o}C)/YSZ. The new bi-epitaxial junctions show RSJ-like I-V characteristics, high critical current density $J_C(10^5\text{-}10^6$ A/cm^2 at T=4.2K) and I_CR_N(1mV). These figures are far better than any other types of bi-epitaxial junctions, thus imply a great potential for device applications. The noise power spectrum of the new $YBa_2Cu_3O_y45^o$ bi-epitaxial Josephson Junctions and dc superconducting quantum interference devices (SQUID) were measured as a function of applied bias current and temperature. The possible noise sources, critical current fluctuations, flux motion noise and resistance fluctuation, are discussed. The results are compared with previous published data for other types of 45^o bi-epitaxial Josephson junctions.

LC26 11 Crossover from Josephson to flux-flow in 10 HTS Grain Boundary Junction R.D. REDWING, *Physics Dept., University of Wisconsin-Madison* B.M. HINAUS, *Physics Dept., Allegheny College* M.S. RZCHOWSKI, *Physics Dept., University of Wisconsin-Madison* B.A. DAVIDSON, *ECE Dept., University of Wisconsin-Madison* J.E. NORDMAN, *ECE Dept., University of Wisconsin-Madison* We observe a crossover in the IV characteristics of 10 bicrystal substrate YBCO grain boundary junctions. At high temperature, the IV characteristic is Josephson-like with well-defined critical current and normal-state resistance. At low temperature, the IV shows characteristics of a superconducting wire (flux-flow). The field-dependence shows evidence for a similar crossover. We further probe the nature of this crossover by sequential Ar anneals that change the critical current by oxygen removal. We find the IcRn product to be independent of the critical current density, indicating that the coupling mechanism is neither SNS nor SIS. We interpret this data in terms of narrow superconducting channels between well-defined dislocations in the grain boundary. The crossover is interpreted as a change in channel length from long to short relative to the (temperature-dependent) Ginzburg-Landau coherence length. A small ratio near Tc leads to Josephson behavior, and a large ratio at lower temperature leads to wire-like behavior.

SESSION LC27: VORTICES IN SUPERCONDUCTORS V: MELTING OF VORTEX ARRAYS

Tuesday afternoon, 23 March 1999
Room 169W GWCC at 13:15
G. Blatter, ETH - Zurich, presiding

13:15

LC27 1 Towards a Theory of Vortex-Lattice Melting in Layered and Continuous Superconductors M.J.W. DODGSON, V.B. GESHKENBEIN, G. BLATTER, *Theoretische Physik, ETH-Zürich, Hönggerberg, 8093 Zürich, Switzerland* We calculate the instability point of the vortex crystal, as a first step towards a theoretical description of melting that goes beyond numerical simulations and the Lindemann criterion. By comparing to simulations,[1] we have found that the self-consistent harmonic approximation (SCHA) greatly overestimates the stability of the vortex lattice. Within perturbation theory about the harmonic approximation, this is seen to be due to the neglect of odd contributions to the lattice-phonon energy, which are the main cause of thermal softening at low temperatures. It has been suggested that an improved self-consistent analysis is constructed from the Dyson equation for the lowest order diagrams,[2] but our analysis shows this also to be unsatisfactory. We suggest a generalized form of the SCHA that includes odd-anharmonic terms. With this new method we find good agreement to the observed anharmonic corrections in simulations, and a reliable stability limit. We find results for 2D crystals, the Bose model of vortices, the full London model of vortices, and pancake-vortices in layered superconductors. We have therefore found a physically transparent method to reliably estimate the melting line in different systems as various parameters are tuned.

13:27

LC27 2 Dislocations and First Order Melting of the Flux Line Lattice JAN KIERFELD, VALERII VINOKUR, *Materials Science Division, Argonne National Laboratory, Argonne, IL** The flux line lattice in type-II superconductors melts in a first order phase transition in the absence of point impurities. Identifying this melting transition with a shear instability, a dislocation-induced *first* order melting transition of the flux line lattice is investigated. We derive an effective free energy for an ensemble of unbound dislocations including effects of both thermal fluctuations and pinning which exhibits a proliferation of dislocations in a first order transition. The resulting melting transitions of the vortex solid and the elastic vortex glass phase (in the presence of point disorder) as well as implications for the phase diagram of high-T_c superconductors and the peak effect are discussed.

*Supported by the NSF-Office of the Science and Technology Center under contract No. DMR-91-20000, by the U.S. DOE, BES-Materials Sciences, under contract No. W-31-109-ENG-38, and by the Deutsche Forschungsgemeinschaft under contract No. KI 662/1-2.

13:39

LC27 3 Melting of two dimensional solids on disordered substrate DAVID CARPENTIER, *LPTENS, 24 Rue Lhmond, 75005 Paris (France)* PIERRE LE DOUSSAL, *CNRS-LPTENS, 24 Rue Lhmond, 75005 Paris (France)* We study 2D solids with weak substrate disorder, using Coulomb gas renormalisation. The melting transition is found to be replaced by a sharp crossover between a high T liquid with thermally induced dislocations, and a low T glassy regime with disorder induced dislocations at scales larger than ξ_d which we compute ($\xi_d \gg R_c \sim R_a$, the Larkin and translational correlation lengths). We discuss experimental consequences, reminiscent of melting, such as size effects in vortex flow and AC response in superconducting films.

13:51

LC27 4 Vortex Phase Diagram Studies on Ultrapure 123 Single Crystals A. ERB, D. ROULIN, A. JUNOD, B. REVAZ, *Département de Physique de la Matière Condensée, Université de Genêve, 24 quai Ernest Ansermet, CH-1211 Genêve 4, Switzerland* C. MARCENAT, C. BOUQUET, R. CALEMCZUK, *Département de Recherche Fondamentale sur la Matière Condensée, CEA-Grenoble, F-38054 Grenoble Cedex 9, France* K. HIRATA, H. SUZUKI, H. ABE, *National Research Institute for Metals, 1-2-1 Sengen, Tsukuba, Ibaraki 305-0047, Japan* We report on magnetization and specific heat measurements up to 28 T on ultra pure (purity $>$ 99.995 %) single crystals of Y-123, Dy-123 and Eu-123 grown in $BaZrO_3$ crucibles. For the fully oxygenated YBCO7 single crystals a first-order like melting of the vortex lattice can be observed in specific heat measurements up to 27 Tesla, which was the highest available field. No terminating endpoint has been detected for those ideally ordered samples. For lower oxygen contents or higher disorder the maximum field at which a first-order like melting occurs is shifted to lower values with increasing disorder. In measurements of the irreversible magnetization no second peak or magnetic fishtail has been observed up to 28 T for the YBCO7 samples while oxygen deficient and less ordered samples show such a peak. Our results on the fully oxygenated samples question the validity of some proposed phase diagrams.

LC27 5 Critical points of the vortex-lattice melting line in $YBa_2Cu_3O_7$, and a possible rotation of the magnetization vector at the melting transition probed by torque magnetometry. A. SCHILLING, M. WILLEMIN, H. KELLER, J. HOFER, *University of Zurich* C. ROSSEL, *IBM Ruschlikon* R.A. FISHER, N.E. PHILLIPS, *LBL and UC Berkeley* U. WELP, R.J. OLSSON, W.K. KWOK, G.W. CRABTREE, *Argonne National Laboratory** We report on thermal and magnetic investigations on the vortex-lattice melting transition in untwinned $YBa_2Cu_3O_7$ in external magnetic fields $\mu_0 H < 18$ T. Above the critical point at $\mu_0 H = 12$ T, the first-order character of the phase transition is lost. Variations in the specific heat are still observed, but they are extremely broadened in temperature. These features are not necessarily related to a second order phase transition, although additional experiments at varying heating and cooling rates do not support a scenario of a glass-type transition. No lower critical point could be observed down to $\mu_0 H = 0.1$ T. We also discuss the possibility that for an off-axis geometry, the first-order transition below the critical point might be accompanied not only by a discontinuity in the magnetization, but also by a simultaneous rotation of the magnetization vector.

14:15

LC27 6 Effect of Low Dose Columnar Defects on Vortex Lattice Melting in Untwinned $YBa_2Cu_3O_{7-\delta}$ W. -K. KWOK, R. J. OLSSON, L. M. PAULIUS*, G. W. CRABTREE, *Materials Science Division and Science and Technology Center for Superconductivity, Argonne National Laboratory, Argonne, Il 60439* Low dose heavy ion irradiation induced columnar defects are studied via transport measurements in several untwinned samples of $YBa_2Cu_3O_{7-\delta}$. The samples were cleaved from a single large crystal, ensuring that all the irradiated samples have the same underlying reference state before irradiation. Columnar defects were created by heavy ions irradiation of 1.4 GeV $^{208}Pb^{56+}$ ions parallel to the c-axis. We compare the transport properties of the crystals before and after irradiation, and demonstrate (i) a sharpening of the first order melting transition after a low does irradiation of B_Φ 50 Oe, (ii) a preferential suppression of the peak effect along the irradiated axis and (iii) an enhancement of the critical current just below the vortex melting line at all fields. In addition, we investigate the suppression of the first order melting transition at higher doses. This work is supported by the U.S. DOE, BES - Materials Science under contract W-31-109-ENG-38(WKK, LMP, GWC) and the NSF-Office of Science and Technology Centers under contract DMR91-20000 (RJO) *Present address: Department of Physics, Western Michigan University

14:27

LC27 7 Separation of the irreversibility line from the first-order melting line in $YBa_2Cu_3O_7$ by an oscillating magnetic field. M. WILLEMIN, *Physik-Institut der Universität Zürich, Switzerland* C. ROSSEL, *IBM Research Division, Zurich Research Laboratory, Rüschlikon, Switzerland* A. SCHILLING, J. HOFER, H. KELLER, *Physik-Institut der Universität Zürich, Switzerland** It is shown that the addition of a weak transverse oscillating magnetic field $\vec{b}_{ac}$ to the main field $\vec{B}$ enhances the relaxation of the vortex lattice of high-T_c superconductors towards its thermodynamic equilibrium. This unique effect is advantageously used to widen the reversible range in the (B,T) phase diagram where torque measurements can well be performed. The first-order vortex lattice melting transition (VLMT) $B_m(T)$ in a high quality untwinned $YBa_2Cu_3O_7$ single crystal has been measured with a sensitive torque technique up to $T/T_c = 0.995$. We

observe that $B_m(T)$ is unaffected by the field $\vec{b}_{ac}$ whereas the irreversibility which sets normally in around and below the VLMT can be completely suppressed. This demonstrates the physical distinction (or separation) which needs to be made between irreversibility and melting lines. This work was performed in collaboration with U. Welp, W.K. Kwok, R.J. Olsson, G.W. Crabtree, A. Erb, and E. Walker.

LC27 8 Signature of the Matching Field in Bose-Glass Melting of Untwinned $YBa_2Cu_3O_{7-\delta}$ Single Crystals A.W. SMITH, H.M. JAEGER, T.F. ROSENBAUM, W.K. KWOK, G.W. CRABTREE, *Argonne National Laboratory* We map out the phase boundary separating the Bose-glass and vortex- liquid phases in an irradiated twin-free $YBa_2Cu_3O_{7-\delta}$ single crystal. We take the phase boundary to be the temperature T_g and magnetic field H at which the crystal begins to screen a small ac magnetic field, h_{ac}. There is a sharp change in slope dT_g/dH of the phase boundary at the matching field B_Φ ($\simeq$ 0.5 T) indicating that interstitial vortices significantly weaken pinning in the Bose-glass state. There is also a pronounced peak in the slope dT_g/dH just below B_Φ at higher h_{ac} which we speculate to be a high temperature remnant of the $T = 0$ Mott-insulator phase. When the field is tilted away from the columns both features disappear, and the glass temperature T_g decreases. The transverse field $H_\perp$ required to melt the Bose-glass follows the power law $|T_g(H_\perp = 0) - T|^{3\nu}$ with a critical exponent ν of approximately 2/3.

14:51

LC27 9 Universal properties for linelike melting of the vortex lattice HENRIK NORDBORG, ALEX KOSHELEV, *Argonne National Laboratory** Using numerical results obtained within two models describing vortex matter (interacting elastic lines (Bose model) and uniformly frustrated XY-model) we establish universal properties of the melting transition within the linelike regime. These properties, which are captured correctly by both models, include the scaling of the melting temperature with anisotropy and magnetic field, the effective line tension of vortices in the liquid regime, the latent heat, the entropy jump per entanglement length, and relative jump of Josephson energy at the transition as compared to the latent heat. The universal properties can serve as experimental fingerprints of the linelike regime of melting. Comparison of the models allows us to establish boundaries of the linelike regime in temperature and magnetic field.

*This work was supported from Argonne National Laboratory through the U.S. Department of Energy, BES-Material Sciences, under contract No. W-31-109-ENG-38 and by the NSF-Office of Science and Technology Centers under contract No. DMR91-20000 Science and Technology Center for Superconductivity.

15:03

LC27 10 Crossing lattices and angular dependence of melting line in very anisotropic layered superconductors ALEX KOSHELEV, *Materials Science Division, Argonne National Laboratory, Argonne, Illinois 60439** We investigate vortex structure and melting transition in layered superconductors with very weak Josephson coupling for fields tilted with respect to the c-axis. We show that even a small in-plane field does not tilt homogeneously the vortex lattice but penetrates inside superconductor in form of the Josephson vortices similar to the Meissner state. At high enough c-axis magnetic field the phase field of an isolated Josephson vortex is essentially built from the phase perturbations created by displacements of the pancake vortices. The crossing-lattices ground state leads to the linear dependencies of the melting field and melting temperature on the in-plane field in agreement with recent experimental observations. At small fields stacks of the Josephson vortices start to accumulate additional pancake strings creating vortex rows with enhanced density. This mechanism explains the mixed chains-lattice state observed by the Bitter decorations.

15:15

LC27 11 The B-T phase diagram of clean extreme type-II superconductors ANH KIET NGUYEN, SAI-KONG CHIN, ASLE SUDBØ, *Norwegian University of Science and Technology* We carry out large scale Monte Carlo simulations on the Ginzburg-Landau model in a frozen gauge approximation to explore the B-T phase diagram of extreme type-II superconductors, with no pinning present. We find strong evidence for a new phase transition line in the vortex liquid in addition to the usual first order FLL melting line. At the new transition temperature, vortex loops, i.e. critical fluctuations renormalize the effective vortex line tension to zero, causing a dramatic change in the properties of the vortex lines. In a 2D boson analogy picture, this corresponds to the bosons loosing their mass at this new phase transition due to vacuum fluctuations, rendering the bose-fluid inherently *relativistic*. This invalidates the mapping from the vortex system to a 2D *non-relativistic* bose-fluid. We also compare our results to experimental results.

15:27

LC27 12 Relation between Hall effect and vortex lattice melting in HTSC superconductors X.-M. ZHU, E. NYEANCHI, *Dept. Experimental Physics, Umea University, SWEDEN** We measure Hall effect and longitudinal resistance in mixed state on HTSC films simultaneously. Our detailed analysis indicates that the sign change in the Hall voltage is related to the change of vortex lattice structure. The results support an interpretation that sign change in Hall voltage is linked with vortex-vortex interaction.

Room 168W GWCC at 13:15
Lui Lam, San Jose State University, presiding

13:15

LC28 1 Surface Reaction Patterns Induced by Dielectric Breakdown: Experiments and Simulations MICHAEL SEIFRIED, *Phys. Dept., San Jose State Univ. and Eberhard-Karls-Universitaet Tuebingen* DAVID S. DAVENPORT, LUI LAM, *Phys. Dept., San Jose State Univ.* Experimental results on surface reaction patterns left on the inner surfaces of conductive plates forming a thin cell are reported. The cell contains oil and is subjected to a vertical uniform electric field. Dielectric breakdown occurs when the electric field exceeds a threshold, which then

induces a chemical chain reaction on the plate, forming filamentary patterns. The details of these tracks are studied. Two computer models – one mimicking the track morphology, the other the detailed structures of the track – will be presented. In both cases, the landscape consists of a diffusing temperature field with sources at the places where chemical reactions occur. The first model is an active walk[1] model, in which a walker goes to places where the temperature is high. The second model is like a forest-fire model, in which new chemical reactions will occur at locations where the temperature is high enough. These models compare well with experiments.

LC28 2 Ostwald ripening: an old selection problem revisited B. MEERSON, *The Racah Institute of Physics, Hebrew University of Jerusalem, Israel* In a late stage of a phase separation, a two-phase mixture exhibits Ostwald ripening (OR). In the small volume fraction limit, OR is describable in terms of the dynamics of a size distribution function $F(R,t)$ of the minority-phase domains. The dynamics are governed by a continuity equation in the R-space subject to conservation of the total volume of domains. A remarkable property of OR, discovered by Lifshitz and Slyozov[1], is self-similarity of $F(R,t)$ and related scaling behavior of its moments at long times. Lifshitz and Slyozov arrived at a "unique" self-similar asymptotics for $F(R,t)$. Later, a whole *family* of similarity solutions was obtained, and an interesting selection problem appeared. I will first report a *weak* selection rule that we have found for this problem[2]. This selection rule relies on a partial information about the initial condition: the asymptotic behavior of $F(R,0)$ in the vicinity of the maximum domain size. Then I will present a *strong* selection rule (in favor of the limiting solution, obtained by Lifshitz and Slyozov) that is provided by an account of fluctuations[3].

LC28 3 Dielectric Breakdown Patterns in Liquid Crystal Films with Various Shapes of Electrodes C.R. SHEU, *Department of Electrophysics, National Chiao Tung University, Hsinchu, Taiwan, R.O.C.* R.P. PAN, *Department of Electrophysics, National Chiao Tung University, Hsinchu, Taiwan, R.O.C.** We apply dc voltage across liquid crystal cells (i.e. Hele-Shaw cells) to induce dielectric breakdown (DB) in the cells. The transparent conducting indium tin oxide (ITO) coatings on the glass substrates are served as the electrodes. The DB patterns left on the glass substrates are similar to that with isotropic fluids macroscopically. However, the detailed local structures are different. Two kinds of shapes (six-linkage circles and rectangles) for ITO electrodes are used. We find that the DB patterns depend on the length to width ratio of the rectangular electrodes. The thickness of DB tracks is related to the cell temperatures. Various surface alignment materials are used to align the liquid crystal molecules in the cells. Time delay of DB is observed in these cells. The mechanisms for both of the pattern formations and time delay will be discussed.

LC28 4 Optical Studies of Intrinsic Fundamental Defects in Self-organized Photonic Crystals YU. A. VLASOV, V.N. ASTRATOV, A.V. BARYSHEV, A.A. KAPLYANSKII, O.Z. KARIMOV, M.F. LIMONOV, G.N. YUSHIN, *A.F.Ioffe Physical Technical Institute, St.Petersburg, Russia** Much efforts has been paid recently to fabrication of a 3D photonic crystal with a full photonic band gap in the visible on the basis ofself-organized synthetic opals. The fundamental limiting factor of this method is the large concentration of plane stacking faults, which are intrinsic to self-assembling growth of colloidal crystal. In worse cases generation of a large number of such defects results in a hexagonal random close packed lattice instead of desired face centered cubic. We have studied the influence of various types of defects of photonic lattice on photonic band structure of synthetic opals by means of optical transmission, reflection and diffraction.

LC28 5 Vortex Formation prior to Martensitic Transformation in a nm-Size Crystal TETSURO SUZUKI, *Tsukuba Institute of Science and Technology, Japan* MASATO SHIMONO, *National Research Institue for Metals, Japan* SHOZO TAKENO, *Osaka Institute of Technology, Japan* Pairs of vortices on the surface of a dislocation free nm-size crystal are found during the numerical experiment to study the microscopic process of the martensitic transformation using molecular dynamics based on EAM potential for Fe due to Johnson and Oh. While the martensitic transformation is known to be easily triggered by dislocations it they are present, formation of pairs of vortices is considered to be a process to introduce dislocations through the surface of a dislocation free nm-size crystal.

14:15

LC28 6 Pattern growth and material failure in shock-driven aluminum cylinders at the Pegasus facility* ELAINE CHANDLER, PATRICK EGAN, *Lawrence Livermore National Laboratory, Livermore, CA*† Experiments on the Pegasus z-pinch facility have studied the growth of inscribed sinusoidal perturbations on the free inner surface of Al 6061-T6 samples undergoing shocked acceleration. Shock pressures were 15 GPa and 50 GPa. The material behind the free surface exhibits massive microspall resulting in a volume of low-density, probably granular, material. The failure mechanism, combined with the forces that cause inertial instability, lead to rapid pattern growth in the failed material and subsequent pattern growth on the surface, including jetting in some cases.

*Work was performed under US DOE Contracts W-7405-ENG-48 and W-7405-ENG-36.

LC28 7 Fluctuation Effects in Steric Reaction-Diffusion Systems ZORAN KONKOLI, *Nordita* HENRIK JOHANNESSON, *Chalmers* BENJAMIN P. LEE, *Bucknell University* We propose a simple model for reaction-diffusion systems with orientational constraints on the reactivity of particles. Its master equation is mapped onto a field theory with upper critical dimension $d_c = 2$ which can be explicitly renormalized to all orders in perturbation theory. To two-loop level the long-time density of particles $N(t)$ is given by the *same* universal expression as for a nonsteric

system, with $N(t) \sim t^{-d/2}$ for $d \leq 2$. For equal initial densities and sufficiently slow internal rotations of the particles our results suggest that steric reactivity supports an intermediate regime where $N(t) \sim t^{-d/4}$, with the crossover to the nonsteric asymptotics determined by the relation between the rates of rotations and reactions. Also, by using field theoretic renormalization group methods it is shown that a two component system exhibits an unexpected memory effect when the diffusion constants are fine tuned to be the same for both orientations: the ratio of the initial densities is ''forgotten'' at early times but ''recalled'' at later times. This effect is rather subtle and hard to observe numerically, and we discuss reasons for this.

14:39

LC28 8 Power-Law Behavior of Long-Range Interacting Solitons L. E. GUERRERO, *Departamento de Física, USB, Apartado Postal 89000, Caracas 1080-A, Venezuela* B. A. MELLO, *IC-CMP, P.O.Box 04513, CEP 70919-970, Brasí lia-DF, Brazil* E. LOPEZ ATENCIO, *Departamento de Física, Facultad Experimental de Ciencias, LUZ, Maracaibo 4011, Venezuela* J. A. GONZALEZ, *Centro de Física, IVIC, Apartado Postal 21827, Caracas 1020-A, Venezuela* We present an analytical and numerical study of a generalized version of the classical sine-Gordon equation, capable of inducing long-range interactions between solitons which can be made as Coulomb-like as desired only by increasing a single parameter n ($n = 1$ recovers the classical sine-Gordon). The long-range property of this model is shown to depend on the ''tail-length'' of the kink formed; also this characteristic gives rise to time dependent power-law behavior quantified by $t^{\frac{1}{1-n}}$, which is directly associated with the long tail phenomenon. For all $n \geq 1$, the interaction length is related to the internal modes of the kink solution. We show that self-affinity extends to all scales for a growth model associated with the proposed equation (a modified long-range sine-Gordon equation with damping and random forcing). Finally, we introduce a generalized version of the Ginzburg-Landau equation which supports long-range topological defects in $D = 1$ and $D > 1$ and present its non-extensivity regimes.

14:51

LC28 9 Dynamics of defect formation ESTEBAN MORO, *Dept. Math. and GISC, Univ. Carlos III de Madrid. Avda. Universidad 30 E-28911, Leganes, Spain* GRANT LYTHE, *CNLS, Los Alamos National Laboratory MS B285, New Mexico 87544 USA* A dynamic symmetry-breaking transition with noise and inertia is analyzed. Exact solution of the linearized equation that describes the critical region allows precise calculation (exponent and prefactor) of the number of defects produced as a function of the rate of increase of the critical parameter. The procedure is valid in both the overdamped and underdamped limits. In one space dimension, we perform quantitative comparison with numerical simulations of the nonlinear nonautonomous stochastic partial differential equation and report on signatures of underdamped dynamics.

15:03

LC28 10 The Impact of a Quenched Random Driving Field on the Three-State Lattice Gas* BENJAMIN N. DWYER, GEETHA SESHAAIYAR, SUSAN R. McKAY, *Department of Physics and Astronomy, U. of Maine, Orono, Maine 04469-5709* This study examines the effects of quenched randomness on the phase diagram of the three-state driven lattice gas. Our simulations show that the striped, low current phases reported in the uniform case[1] are robust and a Gaussian distribution of fields has little impact on the phase diagram until the distribution width is large enough to include a significant probability of fields opposing the original driving direction. Results were obtained on a 30x30 lattice with periodic boundary conditions, with some simulations also run on larger lattices for comparison. In addition to the case of a distribution of fields frozen for the entire run, we also considered the case of a field with values altered on a time scale that is slow compared with that of the local dynamics, to determine the effects of uncontrolled correlations in the randomness arising due to particles repeatedly encountering the same local realization of the quenched randomness[2], which is particularly important in the high current regions.

LC28 11 Pattern Formation in the Drying of Gels* CHEIN-SHIU KUO, *Boston University* RAMA BANSIL, *Boston University* We have initiated video-microscopic experiments to study the drying process in gels, using gelatin gels and inducing the drying process by either changing the temperature or solvent composition. Gelatin gels were cast between microscope slides. The gels were made either in pure water or water/methanol mixtures. By leaving one edge of the sample unsealed a slow drying front propogates through the cell. Either a highly ramified, percolating structure or a discrete fractured, cell-like morphology was observed. It was possible to observe the transition between these two morphologies. The structures appear to depend on the rate at which the solvent evaporates and chemical composition of the solvent. The results will be compared with pattern formation in other fracture related problems.

Room 166W GWCC at 13:15
Kevin Bedell, Boston College, presiding

13:15

LC29 1 Interaction-Induced Enhancement of Spin-Orbit Splitting for 2D Electrons M. E. RAIKH, *The University of Utah* GUANG-HONG CHEN, *The University of Utah* We study theoretically the renormalization of the spin-orbit coupling constant of two-dimensional electrons caused by the electron-electron interactions. We demonstrate that, similarly to the g factor, the renormalization corresponds to the enchancement, although the magnitude of the enhancement is weaker than that for the g factor. For high electron concentrations (small interaction parameter r_s) the enchancement factor is evaluated analytically within the static random phase approximation. For large $r_s \sim 10$ we use an approximate expression for effective electron-electron interaction, which takes into account the local field factor, and calculate the enhancement numerically.

13:27

LC29 2 Spin-Orbit Anomaly in the Dielectric Function of 2D Electron Gas GUANG-HONG CHEN, *The University of Utah* M. E. RAIKH, *The University of Utah* We study the static dielectric function $\varepsilon(q)$ of 2D electron system with spin-orbit coupling in the frame of the random phase approximation. We demonstrate that, in addition to the well-known $2k_F$-Kohn anomaly, spin-orbit coupling gives rise to the novel anomaly in the dielectric function at small $q = q_0 \ll k_F$, where q_0 is the distance between two Fermi surfaces. As a result of this anomaly a large-distance behavior of the potential from a point charge exhibits (in addition to the conventional Friedel oscillations) novel oscillations with a period $2\pi/q_0$. The remarkable feature of these oscillations is that they are not smeared out by the temperature. We show that the small-q anomaly also modifies the indirect exchange interaction of localized magnetic moments (RKKY interaction). In the presense of spin-orbit coupling this interaction acquires a high-temperature component.

13:39

LC29 3 New Results in the Field-Induced Metal-Insulator Transition LOURDES VAZQUEZ, *Boston College* KEVIN BEDELL, *Boston College* We study the consequences of locality for the Fermi Liquid parameters in a magnetic field. We investigate the thermodynamics of a local Fermi liquid in a magnetic field and explore the different ways in which a metal-insulator transition might occur. We discuss the dynamics and collective effects that take place in the presence of the field and in the proximity of a metal-insulator transition.

13:51

LC29 4 Correlation Effects and Transitions in the $NiS_{2-x}S_x$ System* J.M. HONIG, *Purdue University, West Lafayette, IN 47907* The $NiS_{2-x}Se_x$ system is a paradigm for studying correlation effects controlled by adjustment of anion sublattice composition, while keeping the cation lattice and electron density fixed. Electrical resistivity (ρ), magnetic, heat capacity, spectroscopic, and Seebeck coefficient (α) measurements on single crystal specimens[1] are reviewed and interpreted in terms of a band structure diagram involving narrow Ni e_g and S-like $3p\sigma$ bands close to the Fermi level. For $x < 0.30$ the former is split by electron correlation effects; this results in high ρ and low α values at low temperatures T. At higher T the high mobility S band carriers dominate, resulting in a maximum in α with changing T. For $0.35 < x < 0.55$ the e_g band is unsplit at low T but correlation effects force a Mott transition to the insulating state at higher T: ρ rises steeply over a narrow T range and then drops off exponentially at higher T, while α remains small. For $x > 0.60$ the alloys are poor conductors. The implications of this scheme on experiment and theory will be explored.

14:03

LC29 5 Slave fermion theory of confinement in strongly anisotropic systems ALBERTO G. ROJO, *University of Michigan* CARLOS A. BALSEIRO, *Centro Atómico Bariloche and Instituto Balseiro, Argentina* We present a mean field treatment of a strongly correlated model of electrons in a three–dimensional anisotropic system. The mass of the bare electrons is larger in one spatial direction (the c–axis direction), than in the other two (the ab–planes). We use a slave fermion decomposition of the electronic degrees of freedom and show that there is a transition from a deconfined to a confined phase in which there is no coherent band formation along the c–axis.

14:15

LC29 6 Persistence of the bond-charge-spin density wave state in the isotropic two-D, interacting quarter-filled band* S. MAZUMDAR, *U. Arizona* R. TORSTEN CLAY, D.K. CAMPBELL, *U. Illinois* S. RAMASESHA, *I.I.Sc. Bangalore* In low-D systems with nesting , electron-phonon interactions can drive a bond order wave (BOW) or site charge density wave (CDW). Electron-electron interactions generally drive a spin-density wave (SDW). It is widely believed that (i) the three broken symmetries do not coexist; and (ii) for non-1/2-filled bands, the broken symmetries disappear in dimensionality > 1. We have shown that in the *quasi*-1D regime, the BOW, CDW and SDW interact cooperatively in the interacting 1/4-filled band [1]. We now show that *even in the isotropic 2D limit* this cooperative interaction leads to persistence of the BOW-CDW-SDW in the 1/4-filled band, establishing a new mechanism for 2D antiferromagnetism. We discuss the implications of our findings for the related concepts of confinement and charge-spin decoupling, and for superconductivity in organic charge-transfer solids.

14:27

LC29 7 Numerical demonstration of the persistence of a coexisting BOW-CDW-SDW state in the isotropic two-dimensional, interacting 1/4-filled band.* R. TORSTEN CLAY, *U. Illinois* S. MAZUMDAR, *U. Arizona* D.K. CAMPBELL, *U. Illinois* S. RAMASESHA, *I.I.Sc. Bangalore* We demonstrate the persistence of a coexisting BOW-CDW-SDW in the strongly interacting 1/4-filled band in the isotropic 2D regime by combining the results of three different numerical techniques: unrestricted Hartree-Fock, exact diagonalization, and constrained path quantum Monte Carlo. For an intermediate Hubbard U (= 6t) and a range of intrachain nearest-neighbor Coulomb interaction strengths V (=0-2t), we establish that the BOW-CDW-SDW state persists for all values of the interchain hopping integral. We also show that inclusion of interchain nearest-neighbor Coulomb interaction further enhances the stability of this coexisting state.

LC29 8 Nonlocal Dynamical Correlations of Strongly Interacting Electron Systems TH. MAIER, *University of Cincinnati** M. JARRELL, *University of Cincinnati* TH. PRUSCHKE, J. KELLER, *Institut für Theoretische Physik, Universität Regensburg* In order to study the effects of nonlocal dynamical correlations in strongly correlated electron systems we use the recently introduced Dynamical Cluster Approximation. This method is a systematic extension of the Dynamical Mean Field Approximation. It includes short ranged correlations while preserving causality. The technique maps the problem on a self-consistently embedded cluster with periodic boundary conditions. The effective cluster problem is solved by using the Non Crossing Approximation. As a demonstration we study the Hubbard model using various cluster sizes and show the effects of nonlocal correlations on the one-particle level.

14:51

LC29 9 Phase separation and the segregation principle in the spinless Falicov-Kimball model ROMUALD LEMANSKI, *Institute of Low Temperature and Structure Research, Wroclau, Poland* JAMES FREERICKS, *Georgetown University* The simplest statistical-mechanical model of crystalline formation (or alloy formation) that includes electronic degrees of freedom is solved exactly in the limit of large spatial dimensions. Away from commensurate densities, the solutions contain both second-order phase transitions and first-order phase transitions (that involve phase-separation or segregation) which are likely to illustrate the basic physics behind the static charge-stripe ordering in cuprate systems. Nesting effects for the commensurate cases create phase transitions to ordered charge-density-wave phases. We show the full phase diagrams as functions of the interaction strength and the particle densities, and determine the regions where the system segregates.

15:03

LC29 10 Critiquing a quasiparticle Hamiltonian for 2 holes in the 2D $t - J$ model. ROBERT J. GOODING, *Queen's Univ., Canada* ALEXANDER L. CHERNYSHEV, *Queen's Univ., Canada* PAK WO LEUNG, *USTHK, Hong Kong* We summarize a comprehensive examination of two holes propagating in a two-dimensional lattice at half filling, viz. zero hole density. The background electron spins have long-ranged antiferromagnetic order, and the hole motion and spin dynamics are described by the $t - J$ model. Our analytical calculations are based on the canonical transformation familiar to the electron-phonon problem — this is an approach which leads to a quasiparticle Hamiltonian describing spin polarons propagating in the antiferromagnetically ordered phase. We calculate the electron momentum distribution function and the (hole) pair correlation function from this work. We compare these results to our exact diagonalization data for a 32-site square lattice — this allows us to critique the appropriateness of this quasiparticle Hamiltonian. We find good agreement between these two different calculations, lending strong support to the quasiparticle Hamiltonian generated by the canonical transformation. One interesting prediction that follows from our results involves the importance of higher harmonics in the pair wave function.

LC29 11 Dynamic Correlations in the 2D t-J-W Model HIROKAZU TSUNETSUGU, *Inst. Appl. Phys., Tsukuba Univ., Tsukuba, Japan* MASATOSHI IMADA, *ISSP, Tokyo Univ., Tokyo, Japan* Coherence of electron motion in two-dimensional strongly correlated systems near the Mott transition is investigated by numerical calculations of several dynamic correlation functions. Previous exact diagonalization studies on the Drude weight of the 2D t-J model[1] indicate the anomalous dynamic exponent $z = 4$ for the Mott transition with hole doping $\delta \to 0$. This may be responsible for anomalously incoherent behaviors observed in various physical quantities. It was also found that coherence is enhanced in transport properties when the additional electron-pair hopping term, W, is introduced, and the ordinary value of the dynamic exponent, $z = 2$, is recovered. To clarify this change in coherence in more detail, we have numerically calculated single-electron Green's function, dynamic spin and pairing correlation functions for the 2D t-J and t-J-W models by exact diagonalization. We will report how electron dynamics changes its coherence character with the W-term.

LC29 12 A transition to a nearly zero TEP state in the layered $BaCoS_z$ antiferromagnet* B FISHER, J GENOSSAR, L PATLAGAN, G M REISNER, A KNIZHNIK, *Physics Department, Technion, Haifa* S REICH, *Materials and Interfaces, Weizmann Institute of Science, Rehovot, Israel* $BaCoS_2$ is a Mott insulator with a Neél temperature (T_N) close to room temperature. In the ordered AF phase, the magnetic moments are confined in the Co_2S_2 planes, and arranged in alternatingly directed FM chains. We report on resistivity, thermopower (TEP) and susceptibility measurements and on room temperature cell constants of $BaCoS_z$ with *nominal* sulfur content z=1.9, 2.0 and 2.1. The properties for z = 2.1 are intermediate between those for $BaCoS_2$ and $BaCo_{0.9}Ni_{0.1}S_{1.8}$, the later famous for an unusual first-order non-metal to metal transition, upon cooling. The main observations of this work are: (a)sharp bends of $ln(\rho)$ *vs* $1/T$ plots far below T_N, towards resistivities that are weakly (or non-)dependent on temperature and (b)vanishingly small absolute TEP associated with the large resistivities measured at low T. Separately, the (a) and (b) findings are not unique for $BaCoS_z$, but the combination of (a) and (b) is quite unusual. We interpret the transport mechanism in the low temperature regime as tunneling in the Co_2S_2 planes, to nearest neighbors along the FM chains and to next-nearest neighbors in the perpendicular direction.

LC30 1 Similarity between $\rho(T)$ at $B = 0$ and at integer Landau filling factors in a dilute 2D system.* S.V. KRAVCHENKO, *Northeastern University* D. SIMONIAN, K.M. MERTES, M.P. SARACHIK, *City College of New York* T.M. KLAPWIJK, *University of Groningen* We show that the temperature below which Shubnikov-de Haas oscillations become apparent in the dilute 2D electron system in silicon is approximately the same as the temperature below which a ten-fold resistance drop in $B = 0$, associated with the transition to an anomalous conducting state, is observed. The temperature dependence of the resistance is quite similar in $B = 0$ and at Landau level filling factors $\nu = 1$ and 2. We interpret this as evidence that the $B = 0$ drop of the resistance reflects a transition from a non-degenerate "classical" state at relatively high temperatures, $T \sim E_F/k_B$, to a degenerate state with anomalous conducting properties at low temperatures, $T << E_F/k_B$.

LC30 2 The role of spin-splitting in the metallic behavior of a two-dimensional hole gas in GaAs STERGIOS J. PAPADAKIS, E. P. DE POORTERE, H. C. MANOHARAN,*M. SHAYEGAN, *Princeton University, Department of Electrical Engineering* R. WINKLER, *Institut Für Technische Physik III, Universität Erlangen-Nürnberg* Experiments on a constant-density two-dimensional hole system in a GaAs quantum well reveal that the metallic behavior observed in the zero-magnetic-field temperature dependence of the resistivity is correlated with the zero-magnetic-field spin-splitting. We use front and back gates to tune the confinement potential asymmetry (the perpendicular electric field) while keeping the density constant, which tunes the spin-splitting in the two-dimensional hole system through the Rashba effect. Low field magnetoresistance (Shubnikov-de Haas) oscillations are used to measure the spin-splitting. We show that the magnitude of the rise in resisivity with increasing temperature is related to the amount of spin-spitting observed.

LC30 3 Suppression of the metallic behavior in two dimensions by spin-flip scattering* XIANG GUANG FENG, DRAGANA POPOVIĆ, *National High Magnetic Field Laboratory, Florida State University* S. WASHBURN, *Dept. of Physics and Astronomy, University of North Carolina at Chapel Hill* The metal-insulator transition as a function of *disorder* has been studied in a two-dimensional electron system in silicon MOSFETs with a peak mobility $\sim 1\,m^2/Vs$. For a given carrier density n_s, the disorder has been varied by applying substrate bias V_{sub}, and the temperature dependence of the conductivity σ has been measured. It is observed that σ peaks at a certain temperature T_m, and decreases as the temperature T is reduced further. By increasing reverse V_{sub}, we observe a systematic decrease of T_m, i. e. the apparent metallic behavior spreads out towards lower T. We argue that the suppression of the metallic behavior at $T < T_m$ is caused by spin-flip scattering from partially-filled band tail of the upper subband, which is reduced by increasing reverse V_{sub}.

LC30 4 Reentry from the 2D Metallic to the Weakly Localized Phase at High Densities in Si-MOSFETs.*

V.M. PUDALOV, *P.N.Lebedev Physical Institute, Moscow, Russia, and Institut fuer Halbleiterphysik, Johannes Kepler Universitaet, Linz, Austria. E-mail: pudalov@sci.lebedev.ru*

Almost all studies of the metallic phase in two-dimensional carrier systems focused so far on its most striking feature, namelythe exponential strong raise in conductivity, G, as temperature decreases from 0.5 to $\sim 0.05E_F$. The strong raise sets in when the carrier density, n, is above a critical value, $n_{c,1} \sim 10^{11} cm^{-2}$. The origin of this raise is presently under discussions and it is not clear whether or not it is related to quantum physics of interacting carriers in 2D. At temperatures lower than $T^* \sim 0.05E_F$, we have found a crossover from the exponential dependence toa weaker one which is linear in the lnT -scale and is delocalizing, i.e. $dG/dT < 0$. The lnT -dependence corresponds to quantum corrections to the conductivity and might drive the 2D system to a perfect metal as T approaches 0. In order to verify this possibility, we have extended measurements to densities 100x higher than $n_{c,1}$. We have done precise ac- and dc-measurements of the conductivity on a few Si-MOS structures with mobility different by 2x, at low dissipated power and at $T << E_F$. We have found that the prefactor of the lnT - dependence changes sign above a certain density, $n_{c,2} \sim 2x10^{12} cm^{-2}$, thus showing the reentry into a weakly localized state. The behavior of the conductivity around the second ''critical'' density is similar to that around a stable focus point rather than a critical point. In comparison tothe first critical density, the second one, $n_{c,2}$, varies much weaker with sample mobility (r_s = 1.8-1.96). This is true as well for the corresponding conductivity, $G_{c,2} \sim 100\text{-}115e^2/h$, and indicates the existence of an upper limit on the conductivity of the 2D metallic state.

*The measurements have been done in collaboration with G.Brunthaler, A.Prinz and G.Bauer.

LC30 5 The Insulator to Quantum-Hall Transition Near the B=0 MIT in Two-Dimensions Y. HANEIN, D. SHAHAR, H. SHTRIKMAN, *Dept. of Condensed Matter Physics, Weizmann Institute, Rehovot 76100, Israel* J. YOON, C.C. LI, D.C. TSUI, *Dept. of Electrical Engineering, Princeton University, Princeton, New Jersey 08544* The insulator to quantum-Hall (QH) transition and the QH to QH transitions in two-dimensional (2D) systems were the focus of many studies, and their significance is well established. Unlike these B-driven transitions, the density-driven metal-insulator transition (MIT) at $B=0$, recently observed in low-density 2D systems, was unforeseen and its origins are still unknown. In systems exhibiting this MIT, an insulator-to-QH transition is not observed as long as the system is metallic, but becomes apparent when the system is insulting at $B=0$. To improve our understanding of the $B=0$ transition, we conducted a study of the insulator-to-QH transition in low-density 2D hole systems in GaAs.We focused on the evolution of this finite-B transition as the density of the 2D system (p) approached the critical density of the $B=0$ transition (p_c). We found that the value of the critical B of the insulator to QH transition (B_c) monotonically decreases to zero as the density is increased up to p_c. The change in B_c describes a gradual process in which the insulator to QH transition appears to converge with the $B=0$ transition. *A priori*, these two transitions are entirely different, but our results unexpectedly indicate that they are related.

14:39

LC30 6 Parallel magnetic field effect on the metallic phase of 2D holes in $GaAs/Al_xGa_{1-x}As$ JONGSOO YOON, C. C. LI, *Princeton University* D. SHAHAR, *Princeton University & Weizmann Institute, Israel* D. C. TSUI, M. SHAYEGAN, *Princeton University* A recent study [1] of the effect of a B field applied parallel to the 2D electron channel in Si MOSFET has revealed that an arbitrarily weak magnetic field suppresses the metallic phase in the limit of $T=0$. We report investigations of the influence of parallel B field on the metallic phase of an unprecedentedly high mobility ($7 \times 10^5 cm^2/Vs$) 2D hole system (2DHS) in a modulation doped GaAs/AlGaAs heterostructure, which shows a zero B field metal-insulator transition at $r_s = 35$, approximately the theoretically predicted density for Wigner crystallization [2]. As in Si MOSFET, our temperature dependence study of the resistivity shows that a parallel B field suppresses the metallic phase. However, the data indicate that there exists a critical field (B_c) below which the metallic phase persists even in the limit $T=0$. By varying the hole density (p) using a backgate, we find that B_c decreases with decreasing p:$B_c \approx 4$T at $p = 4 \times 10^{10} cm^{-2}$, and $B_c \approx 2 \times 10^{10} cm^{-2}$. [1] D. Simonian et. al., Phys. Rev. Lett. 79, 2304 (1997) [2] J. Yoon et. al., cond-mat/9807235

LC30 7 Strong response to parallel magnetic field of the *insulating* 2D electron system in silicon MOSFET's.* K.M. MERTES, D. SIMONIAN, M.P. SARACHIK, *City College of New York* S.V. KRAVCHENKO, *Northeastern University* T.M. KLAPWIJK, *University of Groningen* We report measurements taken at temperatures between 0.24 K and 1.9 K of the resistance as a function of magnetic field applied parallel to the plane of the dilute two-dimensional system of electrons in silicon MOSFET's. Data will be shown for electron densities ranging from the insulating ($n_s = 0.64 \times 10^{11}$ cm^{-2}) to the conducting (7×10^{11} cm^{-2}) side of the $B = 0$ conductor-insulator transition. Our main finding is that the giant magnetoresistance found previously in the conducting phase persists into the *strongly insulating regime*: there is a large initial increase in resistivity with increasing field, followed by saturation to a value that is approximately constant above a characteristic magnetic field $B_{sat} \sim 1$ Tesla. For example, the resistivity at $T = 300$ mK and at the lowest electron density increases from a zero-field value of $\approx 100\ h/e^2$ to $\approx 1.2 \times 10^3 h/e^2$ at saturation. This is unexpected behavior in an insulator that exhibits ordinary Efros-Shklovskii variable-range hopping in zero field.

LC30 8 Hall coefficient of the 2D electron system in silicon on both sides of the $B = 0$ metal-insulator transition.* D. SIMONIAN, K.M. MERTES, M.P. SARACHIK, *City College of New York* S.V. KRAVCHENKO, *Northeastern University* T.M. KLAPWIJK, *University of Groningen* We report measurements taken between 0.24 K and 1.9 K of the Hall coefficient in the dilute two-dimensional electron system in silicon MOSFET's for electron densities between 0.74×10^{11} and 2.26×10^{11} cm^{-2} spanning the anomalous $B = 0$ conductor-insulator transition. In contrast with the diagonal resistivity ρ_{xx}, which varies strongly with temperature, ρ_{xy} is independent of temperature and linear with magnetic field for fields up to 1 Tesla. The Hall coefficient varies linearly with the electron density determined independently from the positions of the QHE minima and exhibits no unusual behavior around the metal-insulator transition.

LC30 9 Universal Resistance Scaling and Reflection Symmetry at Metal-Insulator Transition D. N. SHENG, Z. Y. WENG, *Univ. of Houston* Inspired by the proposal of Dobrosavljevic *et al.*[1] that the β-function should have a logarithmic dependence in the critical region in order to explain B=0 matal-insulator transition (MIT)[2] with reflection symmmetry, we have studied various well-known MIT systems, including Quantum Hall plateau to insulator transition, 3D Anderson transition in the absence or presence of magnetical fields. We found that although longitudinal conductance scaling may not be universal (when $B \neq 0$), the *longitudinal resistance* has a universal exponential-dependence on L/ξ (L is the sample size and ξ is the scaling variable) independent of the symmetry of Hamiltonians or dimensionality. Reflection symmetry is always present at MIT for all these systems. Our results suggest that there exists a universal scaling law as a general property of MIT's including the 2D $B = 0$ case.[1,2]

LC30 10 Quantum Corrections to the Conductivity of the 2D Metal in Si-MOS* V.M. PUDALOV, *P.N.Lebedev Physical Institute, Moscow, Russia* G. BRUNTHALER, A. PRINZ, G. BAUER, *Institute for Semiconductor Physics, University of Linz, Austria* E.M. DIZHUR, *High Pressure Physics Institute, Troitsk, Russia* We report studies of the spin properties of the 2D metallic state in Si-MOSFETs. At temperatures lower than $\sim 0.05E_F$ and at densities $n > 10^{11} cm^{-2}$, the conductivity G shows adelocalizing logarithmic temperature dependence, with $dG/dT < 0$. We have also measured the weak magnetoresistance R(H) in a perpendicular field, related to single-particle quantum interference. The analysis of the R(H) data yields the phase breaking time and the "localizing" contribution ($C_l > 0$) in the lnT -dependences. Within the resolution of $\sim 10^{-4}T$, no spin-orbit contribution was observed over entire range of T = 0.03 - 2K and densities (r_s = 7 - 1.8). The lnT -dependence persists at r_s from $\sim$ 10 to 1.3 and its prefactor C_T changes sign at $r_s = 1.8$. This is not accompanied by significant changes of the disorder parameter k_F l, and the phase breaking time, which is $\sim$ 1/T. The absence of the spin-orbit coupling on the diffusion length scale and thestrong response to a parallel magnetic field are consistent with an antiferromagnetic but not a ferromagnetic spin-ordering in the 2D plane.

LC31 1 Atomic Force Microscopy of Protein Aggregates - Amyloid Fibrils CRISTIAN IONESCU-ZANETTI, *Physics Dept. UCSC* RITU KHURANA, *Chemistry Dept. UCSC* JOEL GILLESPIE, *Chemistry Dept. UCSC* JAY PETRICK, *Chemistry Dept. UCSC* SUE CARTER, *Physics Dept. UCSC* ANTHONY FINK, *Chemistry Dept. UCSC* The atomic force microscope (AFM) has been shown to be instrumental to the study of biological systems. Here it is used in the study of immunoglobulin light

chain aggregates. These aggreagates are amyloid fibrils, a characteristic feature of a light chain deposition disease, AL amyloidosis. Four different fibrillar structures were observed: single filaments of 2.0 nm diameter, protofibrils of 4.8 nm diameter, and fibrils of 8.6 nm diameter, with a minor population of 6.8 nm. Both fibrils and protofibrils exhibit a braided structure. The fibrils show a peroadicity of 56 and 106 nm. The data suggests a hierarchical structure for AL amyloid fibrils, starting with filaments that form protofibrils, two of which interact to form fibrils.

LC31 2 2D Crystallisation of Annexin V Investigated by Atomic Force Microscopy. ILYA REVIAKINE, WILMA BERGSMA-SCHUTTER, ANNE SIMON, ALAIN BRISSON, *Biophysical Chemistry, University of Groningen, Nijenborgh, 4, 9742 AG Groningen, the Netherlands* Two dimensional (2D) crystals are used for determining the structure of (macro)molecules by electron crystallography. A well established method for the 2D crystallisation of soluble proteins is the so-called lipid monolayer technique, where 2D crystals are formed on a lipid monolayer incorporating a protein-specific ligand spread at the air-water interface (1). While the technique has been used successfully to crystallise a number of proteins, the understanding of the crystallisation process itself was hindered by the lack of suitable experimental approaches. Advent of new techniques, of which Atomic Force Microscopy is one, has already lead to new developments (2) and promises a greater insight into this area. We have utilised the unique ability of AFM to provide molecular-resolution images of biological macromolecules in their native aqueous environment to investigate the process of protein 2D crystallisation on supported phospholipid bilayers. The experimental results of these studies will be presented. 1. Uzgiris, E.E. & Kornberg, R.D., Nature 301, (1983) 125. 2. Reviakine, I., Bergsma-Schutter, W., Brisson, A. J.Struct.Biol. (1998), 121, 356.

LC31 3 A Low Stress Method for Elasticity Measurements of Cells using Atomic Force Microscopy R. MAHAFFY, J. KAS, C. K. SHIH, *Department of Physics, University of Texas at Austin, Austin, TX, 78712* Biological cells demonstrate remarkable elastic properties. Under low stress, a cell is very flexible and can thus adhere to its neighbors, but, as demonstrated by previous atomic force microscopy(AFM) results, the cell can withstand pressures in excess of 10 kPa. This ability of a cell to deform differently to a range of pressures over several orders of magnitude indicates a highly non-linear elasticity. Thus far, elasticity measurements from AFM have been done with a standard tip exerting extremely high pressures on the cell. This limited pressure range is insufficient to study the range of cell elasticity so we have developed a method by which we can study the cells response to lower stresses. By attaching latex beads with sizes ranging from less than 1 micron to 8 microns to the cantilever, we are able to control the pressures exerted by changing the contact area. To establish the accuracy of our modified technique, we have first tested the elasticity of polyacrylamide gel films. Having confirmed the measurement technique on this simple system, we are then able to apply our method to the study of malignant fibroblast and other cell lines with lower pressures and investigate the non-linear elasticity.

13:51

LC31 4 Discrimination of DNA Hybridization Using Chemical Force Microscopy L. MAZZOLA, *Stanford University, Stanford, CA 94305* S.P.A. FODOR, *Affymetrix, Inc., Santa Clara, CA 95051* C.W. FRANK, *Stanford University, Stanford, CA 94305** Atomic force microscopy (AFM) can be used to probe the mechanics of molecular recognition. In the application known as "chemical force" microscopy, the AFM tip can be chemically modified and then used to probe surfaces through chemical recognition. When modified with a biological ligand or receptor, the AFM tip can differentiate the biological binding partner from a surface array. The strength of the interaction between the modified tip and the substrate is mediated by the chemical affinity of the molecular pair. In this work we use chemical force microscopy (CFM) to probe the interaction of short segments of DNA (oligonucleotides). A standard AFM cantilever was modified with the sequence 3'-CAGTTCTACGATGGCAAGTC and then used to scan substrates containing the complementary sequence 5*-GTCAAGATGCTACCGTTCAG. The substrates consisted of micron-scale, patterned arrays of one or more distinct oligonucleotides. When in sliding contact with the substrate, the modified tips exhibit a strong frictional interaction with the surface-bound DNA. The friction force is linear with the applied load and is shown to be proportional to the molecular adhesion. Through friction force imaging, the DNA-modified tips clearly distinguish the complementary oligonucleotide from non-complementary sequences within the patterned array.

LC31 5 STM imaging of DNA adsorbed on Cu(111) surfaces HIROYUKI TANAKA, T. KANNO, CHI. HAMAI, T. KAWAI, *ISIR-Sanken, Osaka University, Mihogaoka, Ibaraki, Osaka, 567 Japan** It has been believed that STM has a potential for sequencing DNA, however STM images of DNA so far are controversial, and many researchers have started using atomic force microscopy instead of STM. Although STM is probably the most promising candidate to image DNA with high resolution, the problems in STM experiment is the low conductivity of the molecules and difficulty in the preparation of specimens. Here we report reliable sub-molecular STM imaging of the single stranded DNA oligomers (5 and 14 bases) and the double stranded DNA (3k basepairs) deposited by a pulse injection method on an atomically flat Cu(111) substrate in UHV. Topographic STM images of DNA oligomers has revealed that the molecules are weakly chemisorbed on the surface with their bases lying flat on the surface. The internal structure of the molecules corresponding to each base and unmistakable helix structure of the double stranded DNA adsorbed on the well-defined Cu(111) metal surfaces have been observed.

LC31 6 High Resolution SQUID Magnetometer for Imaging Biomagnetic Fields* F.J. BAUDENBACHER, N.T. PETERS, J.P. WIKSWO, *Vanderbilt University* M. RADPARVAR, *Hypres, Inc.* Biological systems present a challenge to scanning Superconducting Quantum Interference Device (SQUID) magnetometers (SSMs) due to the weakness and distributed nature of many of the interesting field sources, *e.g.*, a field resolution of a few hundred $fT/\sqrt{Hz}$ and spatial resolution of 100 μm to 300 μm are needed for magnetic imaging of action and injury currents in isolated

tissue. To achieve the highest field sensitivity with a 300 μm spatial resolution, we developed a low-temperature superconductivity (LTS) thin-film SQUID with integrated pickup-loops. A four-turn pickup-loop and a one-turn balance coil forms an asymmetric gradiometer with a 3 mm baseline. A flux transformer couples the flux difference to a double-loop SQUID sensor. The flux noise of the device is 2.3 $\mu\phi_0/\sqrt{Hz}$ above 0.5 kHz, resulting in a field sensitivity of 130 fT/$\sqrt{Hz}$. The SQUID chip is mounted in the vacuum space of a helium cryostat behind a 50 μm sapphire window, resulting in a 70 μm spacing between a room temperature sample and the edge of the SQUID chip. Tests on a photolithographic wire pattern demonstrate a 300 μm spatial resolution. Initial biological results will be presented.

LC31 7 A Quantum Leap in Human Magnetic Resonance: Imaging at 8.0 Tesla AMIR M. ABDULJALIL, ALLAHYAR KANGARLU, *The Ohio State University* A human magnetic resonance imaging system has been constructed which operates at a field strength of 8.0 Tesla and has a room temperature bore of 80 cm. This system has overcome fundamental technological and scientific hurdles. The magnet itself contains the most stored persistent magnetic energy in the world (81 MJoules). It is wound from 414 km of NbTi wire and operates at 4K. Its internal windings withstand 21 kpsi of stress. Initial results demonstrate that anticipated complications in RF penetration depth, RF power requirements, RF coil design and dielectric resonances were surmountable. In this work, the first imaging results acquired from the human brain at 340 MHz will be presented. We have obtained high resolution images (256x256, 512x512, 1024x1024) which display excellent image quality. In addition, these images do not display the center brightness that has characterized images obtained at 4 Tesla. Moreover, the 8 Tesla images display the phenomenal potential for imaging at very high fields for imaging and spectroscopic experiments involving the proton and other biologically significant nuclei. In this presentation we will show that, in a real sense, these images have made a major contribution to this discipline and have enhanced our fundamental understanding of magnetic resonance.

LC32 1 Topology of Chaotic Attractors in a Hodgkin-Huxley model, or Why is a Rat Coldreceptor Like a YAG Laser?.
ROBERT GILMORE, *Drexel University**

The Hodgkin-Huxley equations were originally developed to model the time evolution and propagation of electrical pulses along the axon of a giant squid neuron. They have recently been modified by Braun and coworkers[1] to describe neural spike train data experimentally observed in dogfish, catfish, and facial coldreceptors of the rat. The output of the modified equations shows a series of sharp voltage spikes of almost equal height, followed by a return to a deep repolarization minimum. The number of spikes in a spike train burst decreases from six to one as the temperature is increased from 10°C to 25°C. A bifurcation diagram shows an alternation between periodic and chaotic behavior, in which the number of spikes per burst is not predictable. In order to determine the type of chaotic behavior generated by the modified Hodgkin-Huxley equations, a topological analysis[2] was carried out. Unstable period one and two orbits have been extracted from the signal and their topological organization has been determined. We find that the strange attractor, and its evolution, is identical to one which has previously been observed in a YAG laser, and which has been called a 'gateau roulé' or 'jelly role.'[3]

LC32 2 Spike Train reveals Low Dimensional Behaviors in a Hodgkin Huxley Neuron with Intrinsic Oscillator* XING PEI, *Center for Neurodynamics, UMSL* ALEXANDER NEIMAN, FRANK MOSS, WINFRIED WOJTENEK, LON WILKENS, *Center for Neurodynamics, UMSL* MARTIN HUBER, MATHIAS DEWALD, HANS BRAUN, *University of Marburg* Low dimensional behaviors of nerve systems are of interest to reveal the dynamics of the ion currents and membrane potentials. However, in many experimental situations the only information available is the spike timing. Is this information sufficient to describe the underlying dynamics? By numerical simulation of a Hodgkin-Huxley model with intrinsic oscillator, the dynamics of the spike time intervals (STI) is compared with the trajectories of the system. The dynamics of STI resembles the main characteristics of dynamics of the system. It represents a subset of the Poincare sections and is similar to a subset of amplitude maps (e.g. slow sodium channel) (similar to Lorenz Map). Bifurcations, limit cycles, chaos are revealed in STI as in the Poincare section. The eigenvalues from STI and from the Poincare section are identical. The correlation dimensions are similar too. Thus, the information of STI sufficiently uncovers the dynamics of the Hodgkin-Huxley neuron.

LC32 4 The Density of the Eigenvalues of UPO's in Noisy Dynamical Systems* KEVIN DOLAN, *University of Missouri, St. Louis* Statistical methods for detecting the presence, and properties of UPO's in noisy data are of great importence, both for the determination of dynamical properties of a system, and for the control of a chaotic, or high period noisy system. We use a very simple statistical algorithm based on phase space topology to determine the presence of UPO's in data. This method produces a distribution of unstable eigenvalues for the UPO, which can then be used to determine the actual unstable eigenvalue of the UPO. This method is very fast, making it useful for real time control. This distribution can also be compared to the results from surrogates, to decide if there really is an UPO present or not.

LC32 5 Electroencephalograms in Epilepsy: Analysis and Seizure Prediction within the Framework of Lyapunov Theory HANS R. MOSER, PETER F. MEIER, *Physik-Institut, Universität Zürich, CH-8057 Zürich, Switzerland* BRUNO WEBER, HEINZ G. WIESER, *Dept. of Neurology, University Hospital, CH-8091 Zürich, Switzerland* Epileptic seizures are defined as the clinical manifestation of excessive and hypersynchronous activity of neurons in the cerebral cortex and represent one of the most frequent malfunctions of the human central nervous system. Therefore the search for precursors and predictors of a seizure is of utmost clinical relevance and may even guide us to a deeper understanding of the seizure generating mechanisms. We extract chaos–indicators such as Lyapunov exponents and Kolmogorov entropies from different types of electroencephalograms (EEGs): This covers mainly intracranial EEGs (semi–invasive and invasive recording techniques), but also scalp-EEGs from the surface of the skin. Among the analytical methods we tested up to now, we find that the spectral density of the local expansion exponents is best suited to predict the onset of a forthcoming seizure. We also evaluate the time–evolution of the dissipation in these signals: It exhibits strongly significant variations that clearly relate to the time relative to a seizure onset. Further, we investigate interictal EEGs (i.e., far away from a seizure) in order to characterize their more general properties, such as the convergence of the reconstructed quantities with respect to the number of phase space dimensions. Generally we use multichannel reconstruction, but we also present a comparison with the delay–embedding technique.

14:39

LC32 6 Detection of Condition Change in Nonlinear Time Series Using a Connected-Phase-Space PDF PAUL GAILEY, *Energy Division, Oak Ridge National Laboratory* LEE HIVELY, *Engineering Technology, Oak Ridge National Laboratory* VLADIMIR PROTOPOPESCU, *Computer Science and Mathematics, Oak Ridge National Laboratory* Temporal variations of biological parameters are often both complex and nonstationary. While nonlinear reconstruction and other approaches can be used to attempt analysis of such data, it is sometimes only necessary to detect substantial changes in the underlying processes. For example, there is evidence that epileptic seizures are preceded by changes in EEG and that seizure prediction may be possible. We report a new technique for detecting small changes in nonlinear time series data. A probability distribution function (PDF) is defined for transitions between discrete regions of phase space. This connected-phase-space PDF (CPS-PDF) is constructed for a reference subset of the time series and continuously compared to subsequent subsets to detect changes. We present results of application of the CPS-PDF technique to model and human EEG data. These results show that the proposed method is more sensitive than the standard nonlinear discriminators.

14:51

LC32 7 Genetic Correlations in Mutation Processes E BEN-NAIM, *Theoretical Division, Los Alamos National Laboratory* We investigate the role of the genetic structure in branching processes with mutation. Generally, correlations decay exponentially with the generation number. However, two distinct regimes of behavior exist. For mutation rates smaller than a critical rate, the underlying structure is irrelevant, while for mutation rates higher that this critical rate lead to strong structure-dependent correlations. This critical behavior underlies all multiple point correlations.

15:03

LC32 8 Mutual Synchronization of Molecular Turnover Cycles in Small Confined Populations of Allosteric Enzymes ALEXANDER S. MIKHAILOV, PEDRO STANGE, *Dept. Physical Chemistry, Fritz-Haber-Institut der MPG, Berlin, Germany* BENNO HESS, *Max-Planck-Institut fuer medizinische Forschung, Heidelberg, Germany* In submicrometer reaction volumes, containing hundreds of allosteric enzymes, diffusive transport and mixing times of regulatory molecules are shorter than the characteristic times of conformational transformations. An enzymic reaction can then be viewed as a collective dynamical process in a population of cyclic molecular machines coupled through fast traveling regulatory molecules. External synchronization of the cycles of individual enzyme molecules by periodic light flashes has recently been experimentally demonstrated [Phys. Rev. E 56 (1997) 7116]. Our theoretical analysis for simple stochastic models of several different product-regulated allosteric reactions shows that the synchronization can spontaneously develop in small enzymic populations in absence of external forcing, as a consequence of interactions between the enzymes [J. Phys. Chem. B 102 (1998) 6273]. It is revealed in rapid spikes of the product concentration with the period controlled by the mean turnover time of single enzymes. The effect is a molecular-level analog of the nonlinear synchronization behavior that was previously known only for macroscopic biological oscillators and neural networks.

15:15
LC32 9 A Minimal Model for Complex Dynamics in Biochemical Reaction Pathways SUGUNA CHALLA, *CCMB* SOMDATTA SINHA, *CCMB* Biochemical reactions are highly nonlinear molecular processes comprising positive or negative feedback and feedforward loops which underlie cellular processes in the living cell. Negative feedback processes ensure stability and conservation of cellular economy. Positive feedback plays an important role in switching and rapid response processes. Though many cellular functions display equilibrium behaviour, periodic and chaotic dynamics are also observed. In reality these reactions are evolutionarily designed and have multiple steps with alternative branches. In this work, we aim to see if a skeletal pathway incorporating the minimal combination of positive and negative feedback processes, representing stability and sensitivity properties, can exhibit a multitude of dynamics from equilibrium to chaos as observed in reality. We show that the simple pathway not only exhibits equilibrium and periodic dynamics, but also shows birythmicity, complex oscillations, chaos and other complexities like fractal boundaries and fractal dimension. We characterise the system in phase space and study the basins of attraction, Poincare section and return map.

15:27
LC32 10 Qualitative results for solutions of the steady Fisher–KPP equation P. M. JORDAN,*ASHOK PURI, *Physics Department, University of New Orleans* In this work we employ several recent theoretical tools from nonlinear analysis to obtain important qualitative information on solutions of the Dirichlet problem for the steady-state Fisher–KPP equation. In particular, we investigate the boundary value problem

$$-\nabla^2\rho = P(\rho) + f(\mathbf{r}), \text{for} \mathbf{r} \in \Omega, \text{with} \rho = 0 \text{on} \partial\Omega,$$

where $\rho = \rho(\mathbf{r})$ denotes a population density, the logistic term $P(\rho)$ is a second or third degree polynomial such that $P(0) = P(1) = 0$, and $\Omega \subset \mathbf{R}^N$ is the habitat, with emphasis on the case $N = 3$. Conditions under which there exists a unique positive solution are determined. This solution is then shown to be decreasing and spherically symmetric for spherical Ω. In addition, conditions are established so that the population occupying Ω is bounded. Lastly, a brief discussion of other applications for equations of the Fisher–KPP type is given.

LC33 1 From pico to seconds: Surface Growth with Kinetic Monte Carlo/Molecular Dynamics.
JOACHIM JACOBSEN, *Haldor Topsoe A/S, Nymollevej 55, DK-2800 Lyngby, Denmark.**

We present a new method for simulating crystal growth by energetic beam deposition. The method combines a Kinetic Monte–Carlo simulation for the thermal surface diffusion with a small scale molecular dynamics simulation of every single deposition event. We have implemented the method using the effective medium theory as a model potential for the atomic interactions, and present simulations for Ag/Ag(111) and Pt/Pt(111) for incoming energies up to 35 eV. The method is capable of following the growth of several monolayers at realistic growth rates of 1 monolayer per second, correctly accounting for both energy–induced atomic mobility and thermal surface diffusion. We find that the energy influences island and step densities and can induce layer–by–layer growth. We find an optimal energy for layer–by–layer growth (25 eV for Ag), which correlates with where the net impact-induced downward interlayer transport is at a maximum. A high step density is needed for energy induced layer–by–layer growth, hence the effect dies away at increased temperatures, where thermal surface diffusion reduces the step density. As part of the development of the method, we present molecular dynamics simulations of single atom–surface collisions on flat parts of the surface and near straight steps, we identify microscopic mechanisms by which the energy influences the growth, and we discuss the nature of the energy–induced atomic mobility.

LC33 2 RHEED comparison of ultrathin Cu films grown with hyperthermal ions and thermal deposition J. POMEROY, A. JUDY, E. BUTLER, J. SETHNA, B. COOPER, *Cornell Center for Materials Research, Cornell University* Hyperthermal copper ion depositions are compared with simulations of other noble metals which predict a narrow energy window between 15 and 25 eV where growth of ultrathin films occurs in a layer-by-layer manner. (Jacobsen, et. al. PRB **58** 23, 1998.) Copper ions are deposited using a plasmatron ion beam system. The growth modes are compared with thermally deposited neutral copper using reflecting high energy electron diffraction (RHEED) to measure intensity oscillations in the anti-phase scattering condition. The sample is prepared by sputtering with energetic argon ions followed by an annealing cycle, and then held at a constant temperature with liquid nitrogen flow. The beam energy is tunable from a few eV to greater than 1 keV with a FWHM of 3 eV in the region of interest, allowing the sensitivity of the growth mode to the energy to be investigated. Rutherford backscattering analysis (RBS) verifies that the mass-selected deposition beam contains fewer than 1/1000 residual impurities. Supported by CCMR (NSF-DMR-9632275) and AFOSR (F49620-97-1-0020).

LC33 3 Mechanisms of Surface Smoothing During Sputter-Induced Ripple Formation on SiO_2 C.C. UMBACH, *Cornell Univ., Dept. of Materials Science* R.L. HEADRICK, *Cornell High Energy Synchrotron Source* B.H. COOPER, *Cornell Univ., Dept. of Physics* J.M. BLAKELY, *Cornell Univ., Dept. of Materials Science* E. CHASON, *Brown Univ., Div. of Engineering* Nanometer-scale ripples have been formed on thermally-grown SiO_2 by argon ion sputtering. Varying the ion energy between 0.5 and 2 keV produced linearly increasing ripple wavelengths between 150 and 600 Å. During sputtering the specular reflectivity and the diffuse intensity of 11 keV x-rays were measured, allowing a determination of aspects of the ripple morphology. The effects of annealing during and after sputtering have also been monitored. The atomic-scale nature of the sputter-induced roughness is evident in atomic force microscope images. Ripple development has been attributed to the surface becoming unstable to the formation of pits during sputtering (Bradley and Harper, JVST A 6, p. 2390. 1988). Several mechanisms for the surface smoothing that opposes this instability have been proposed, including ion-enhanced diffusion (Mayer, Chason and Howard, JAP, 76, p. 1633 (1994)) and diffusionless smoothing (Makeev and Barabasi, APL, 71, p. 2800 (1997)). The plausibility of these smoothing mechanisms will be discussed in the context of the x-ray scattering and AFM observations.

LC33 4 Nanocluster Growth Under the Influence of Coulombic Forces* JOHN WENDELKEN, *Oak Ridge National Laboratory* WOEI-WU PAI, *The University of Tennessee* ZHENYU ZHANG, *Oak Ridge National Laboratory* Many system dependent techniques have been explored to produce nanoclusters with controlled sizes. We present here experimental support for a recent theory[1] in which coulombic forces between forming nanoclusters are predicted to lead to a cluster size distribution which is narrower, peaked at a smaller size, spatially more ordered, and largely system independent. To allow 3-D cluster formation and to free the system from kinetic and stress constraints when depositing B on A, the technique of buffer layer assisted growth[2] is utilized in which a temporary buffer layer of Xe is condensed on the surface of A before deposition of B. We add a flux of low energy electrons incident on the surface while B is deposited to induce a coulombic repulsion between the growing nanoclusters. Initial results are encouraging with the formation of 3-D Fe clusters on Cu(111) showing the predicted change in size distribution.

LC33 5 Surface Modification to promote Semiconductor-Insulator Heteroepitaxy B.R. SCHROEDER, SHUANG MENG, A. BOSTWICK, MARJORIE A. OLMSTEAD, *Department of Physics, University of Washington* The heteroepitaxial growth of laminar, crystalline silicon on CaF_2(111) substrates is hindered by two factors 1) CaF_2 surface energy is much lower than that of Si and 2) a strong etching reaction between Si and F. We propose two methods to overcome these difficulties 1) use of arsenic as a surfactant 2) electron irradiation to remove surface fluorine. Low energy (40 eV) electron irradiation removes fluorine (amount of F removed scales linearly with the electron dose) but the films become extremely reactive with oxygen and/or water vapor (even under UHV conditions). Arsenic does not stick to unirradiated CaF_2 at room temperature but it does bond to irradiated CaF_2 (approx. 1 monolayer F removed), presumably at surface defect sites. At room temperature As remains on the surface, but it diffuses into the bulk at 400 °C. This indicates that F centers are created in the bulk as well as on the surface. Supported by DOE grant DE-FG03-97ER45646/A002.

LC33 6 Ab initio study of surface structure and core level shifts in PbS (001)* STEFANO DE GIRONCOLI, *INFM - Scuola Internazionale Superiore di Stud[\]fi Avanzati (SISSA) via Beirut 2-4, 34014 Trieste, Italy* ALESSANDRA SATTA, *INFM - Dipartimento di Fisica, Universitá di Cagliari, Cagliari, Italy* Lead sulfide, a semiconductor compound with rocksalt structure, naturally occurs as the mineral galena. A large body of experimental data on PbS (001) surface is available at present. Measurements on freshly cleaved (001) surfaces of PbS give no evidence of atomic reconstruction, although atomic relaxation has been invoked in order to explain the experimental absence of surface core level shifts in this mineral. An accurate theoretical study of the structural and electronic properties of PbS (001) non-polar surface is therefore timely, since a controversial debate on the amount of surface relaxation is still open. In this work the structure, the relaxation properties and the surface core level shifts of PbS (001) surface are studied in some details via *ab initio* pseudopotential calculations.

LC33 7 Studies of Interface Morphology of CdS Thin Films Grown on Cadmium Stannate and Glass Substrates by Grazing Incidence X-ray Scattering Y.H. KAO*, S. HUANG , Y.L. SOO , M. BECHMANN , *SUNY at Buffalo* X. WU , T.J. COUTTS , R. DHERE , H.R. MOUTINHO , *National Renewable Energy Laboratory** The interface between CdS and front collector transparent conducting material plays an active role in many photovoltaic applications, physical understanding and control of the interface morphology are needed. Cadmium stannate (Cd_2SnO_4) has been recognized as an important transparent conducting material in light of its superior physical properties. The grazing incidence X-ray scattering (GIXS) technique is very useful for nondestructive characterization of the interface morphology of layered structures, thus it is well suited for this purpose. In this work, various thin films of CdS deposited on cadmium stannate and glass substrates have been investigated by the GIXS technique using synchrotron radiation. Variations of surface and interfacial roughness as well as lateral correlation lengths as functions of film thickness and processing conditions will be presented.

LC33 8 Polarity Conversion in CdTe/Bi(Sb)/CdTe Heterostructures S. CHO, A. DIVENERE, Y. KIM, G. K. WONG, J. B. KETTERSON, *Department of Physics and Astronomy and Material Research Center, Northwestern University, Evanston, IL* In zinc-blende of semiconductors (such as InSb, GaAs, and CdTe, etc.), the two (111) faces, designated by A and B, are different and polar. In the growth of CdTe on Bi(Sb)/CdTe(111)B, the polarity of CdTe can be controlled by changing Bi or Sb thicknesses. For films with Bi thicknesses of less than 15 Å or Sb thicknesses of less than 40 Å, the CdTe displays a B (Te- terminated) face,

whereas above these thicknesses it displays an A (Cd-terminated) face. On the other hand, a CdTe layer grown on Bi(Sb)/CdTe(111)A always displays an A face regardless of the Bi or Sb layer thicknesses. This polarity conversion, which occurs between the CdTe layers, may be explained by the electric dipole-dipole interaction. In the case of ultrathin Bi or Sb layers on CdTe(111)B, the polarity can be reversed to display a B face due to the strong repulsive force between the oppositely directed dipoles. In the growth of the CdTe(111)/Bi(Sb)/CdTe(111)A system, the final CdTe layer always has A(Cd-terminated) face due to the parallel direction of the two dipoles. This work is supported by DARPA under Grant No. DAAG55-97-1-130.

LC33 9 Interface Morphology and Migration of Cu and Se Atoms in Heterojunctions Formed Between CdS and Single Crystal of $CuInSe_2$ Y.L. SOO , S. HUANG , Y.H. KAO*, *SUNY-Buffalo* S.K. DEB , K. RAMANATHAN , *National Renewable Energy Laboratory* T. TAKIZAWA , *Nihon University, Japan** Angular dependence of x-ray fluorescence (ADXRF), x-ray absorption fine structure (XAFS), and grazing incidence x-ray scattering (GIXS) measurements were carried out using synchrotron radiation for a study of the interface morphology and migration of constituent atoms in heterojunctions formed between CdS and single crystal of $CuInSe_2$. The single crystal samples avoid the usually complicated problems due to multiple phases of the Cu-In-Se compounds. Prominent features in our ADXRF data clearly demonstrate that both Cu and Se atoms have migrated into the CdS layer in the heterojunction while In atoms remain intact in the $CuInSe_2$ single crystal. The local structures around Cu in the system also show significant changes after the deposition of CdS, as manifested by the XAFS spectra.

**The present research at SUNY-Buffalo is supported by DOE and NREL.

LC33 10 Sulfur Diffusion in Pollycrystalline Thin Film CdTe Solar Cells M.H. ASLAN, R.T. COLLINS, W. SONG, J. TANG, D. MAO, *(Physics Dept. Colorado School of Mines)* D.H. LEVI, R.K. AHRIENKEL, *(National Renewable Energy Laboratory)* S.C. LINDSTROM, M.B. JOHNSON, *(University of Oklahoma)* We have studied S diffusion from CdS into CdTe during post growth annealing of thin-film CdS/CdTe heterojunction solar cells. Measurements made by Photoluminescence (PL) and X-Ray Diffraction (XRD) show the presence of two distinct $CdTe_{1-x}S_x$ phases within the CdTe film. Interdiffusion occurs during an annealing step following a $CdCl_2$ treatment. We have profiled the S composition as a function of depth by sequentially etching the film followed by PL and XRD measurements. This was done at different annealing temperatures. We find that as we approach the CdS interface, the ternary phase becomes dominant. For samples annealed at 350 °C, S concentration in the ternary phase is 1-2% near the interface. At 410 °C, which corresponds to the optimal annealing temperature for high efficiency devices, the S concentration increases from $< 1\%$ at the back face to 4-5% near the CdS/CdTe interface. The 460 °C annealed sample shows around 5% S content throughout the CdTe layer. Auger Electron Spectroscopy (AES) measurements confirm these results.

LC34 1 Biopolymer Physics of Chromosome Folding and Disentanglement.

JOHN F. MARKO,* *University of Illinois at Chicago, Departments of Physics and Bioengineering*

The DNAs of eukaryote chromosomes are the longest linear polymers known, those of human cells being centimeters in length. I will describe recent applications of ideas from polymer physics to the description of chromosomes in cells, focusing on the problems of how they are folded and therefore compacted, and how they are disentangled and segregated. In eubacteria (e.g. E. coli) the millimeter- long chromosome is tethered to itself to form roughly 100 'loop' domains, each independently supercoiled. The domains compact the chromosome [1], while supercoiling plays an important role in entanglement removal [2]. In eukaryote cells (animals, plants, fungi) chromosomes are made of 'chromatin fiber', a DNA+protein composite filament. Static and dynamic studies indicate that chromatin in vivo displays flexible polymer phenomenology. Segregation of chromosomes during their condensation at the onset of cell division follows from these polymer-like properties, combined with the apparent chromatin folding scheme [3]. Recent micromanipulation studies of the elasticity of single mitotic chromosomes will also be discussed. This research was supported in part by a Biomedical Engineering Research Grant from The Whitaker Foundation and by Grant DMR-9734178 from the NSF. 1. N. Trun and J.F. Marko, Amer. Soc. Microbiol. LC34 2 Structure and Interactions of Supramolecular Phases Probed by X-ray Scattering.

TIM SALDITT, *Sektion Physik der Universitaet Muenchen, Germany*

We present recent work on high resolution x-ray scattering from self-assembled supramolecular structures of biological macromolecules. The quantitative lineshape analysis of the diffraction pattern can reveal important information on the structure as well as on the statistical fluctuations. From typical experiments at modern synchrotron sources, elastic coefficents can be extracted, which in turn reflect the relevant interactions on the molecular scale. Examples of pure phospholipids, lipid-DNA, and lipid-peptid systems will be discussed.

14:27
LC34 3 Theory of DNA-Lipid Self-Assembly.
ROBIJN BRUINSMA, *Department of Physics, University of California, Los Angeles*

Aqueous mixtures of DNA and cationic lipids produce both lamellar and hexagonal complexes of considerable significance for gene therapy. These complexes exhibit exotic electrostatic phenomena such as spontaneous overcharging, and an isoelectric instability. The talk will present the Poisson-Boltzmann theory of the complexes and compare the results with recent X-ray Synchrotron studies. Spontaneous overcharging will be shown to be a more general property of macro-ion self-assembly that also can be applied to DNA-histone complexation. The preferred fusion of hexagonal complexes with anionic liposomes will be analysed in the light of the unusual electrostatics.

15:02
LC34 4 Structure and Interactions in DNA and Lipid Membrane Assemblies.
RUDI PODGORNIK, *Laboratory of Physical and Structural Biology, NICHD, National Institutes of Health, and Department of Theoretical Phsyics, J.Stefan Institute*

The phase diagram and the corresponding equation of state for DNA in condensed phases will be presented and compared to the equation of state of a multilamellar membrane assembly. The importance of thermally driven conformational fluctuations will be assesed for both systems and their concequences for the equation of state of DNA and membrane assemblies will be compared in detail. The main difference in behaviors of the two systems stemms as much from a different internal geometry (1D for polymers vs. 2D for membranes) as well as from the fact that in condensed DNA phases the positional order is short ranged (liquid like) while it is quasi long ranged (smectic) in membrane assemblies.

LC35 1 Evidence for Charge Stripes in Cuprates from Scattering Studies.
JOHN M. TRANQUADA, *Physics Department, Brookhaven National Laboratory, Upton, NY 11973-5000**

The most direct evidence for charge stripes in doped cuprates has come from neutron and x-ray scattering studies of the system $La_{1.6-x}Nd_{0.4}Sr_xCuO_4$. The neutron measurements reveal two sets of elastic incommensurate superlattice peaks, one corresponding to charge order and the other to magnetic order. The early studies focused on a single crystal with $x = 0.12$, where superconductivity is strongly depressed, but more recently we have demonstrated the presence of elastic (or quasielastic) magnetic peaks in samples covering a considerable range of x.[1] The charge order scattering in the $x = 0.12$ sample has been confirmed by high-energy x-ray scattering.[2] Of particular interest is the $x = 0.15$ concentration, where high-field-magnetization and muon-spin-rotation studies,[3] in combination with the neutron scattering results, demonstrate that superconductivity and stripe order coexist intimately. The reason for static stripe correlations in the Nd-doped system is pinning by a special structural modulation of the CuO_2 planes. Similar static magnetic order has also been observed in Zn-doped samples. The connection with the dynamic magnetic correlations found in other cuprate superconductors will be discussed.

LC35 2 Antiferromagnetic order and static stripe order in $(La,Eu)_{2-x}Sr_xCuO_4$.
BERND BÜCHNER, *II. Physikalisches Institut, Universität zu Köln, Germany**

Experimental results for the magnetic and transport properties of poly– and single crystalline $(La,Eu)_{2-x}Sr_xCuO_4$ for $0 \leq x \leq 0.2$ and Eu contents up to 0.2 are presented. Due to the Eu doping a low temperature tetragonal (LTT) phase occurs in the entire range of Sr concentrations. Thus it is possible to investigate the change from the usual antiferromagnetic state at $x = 0$ to the stripe ordered phase which is present in the LTT phase at elevated levels of Sr doping. Our measurements of the high field magnetization, ESR, and μSR reveal clear differences between the two different kinds of static magnetic order. The usual antiferromagnetic state at small hole content is similar to that in $La_{2-x}Sr_xCuO_4$, i.e. T_N strongly decreases upon Sr doping due to the presence of mobile holes. The structural transition to the LTT phase

even enhances the Cu spin dynamics. However, for $x > 0.04$ the dynamics of the spin fluctuations is strongly suppressed in the LTT phase and static magnetic order occurs due to the formation of static spin and charge stripes. T_N increases with increasing hole doping for $0.04 < x < 0.15$. Moreover, the signatures of this static stripe magnetic order which is present in compounds with a rather large conductivity clearly differ from the findings at the antiferromagnetic transition at low doping. Following T_N for the magnetic stripe order as a fucntion of x yields a surprising correlation. Remarkably, both, the absolute values of T_N as well as its strontium concentration dependence are very similar to the findings for T_c in $La_{2-x}Sr_xCuO_4$ superconductors where inelastic neutron scattering suggests dynamic stripe correlations for $x \geq 0.05$.

LC35 3 Local Charge Structure and High-T_c Superconductivity.
VICTOR J. EMERY, *Department of Physics, Brookhaven National Laboratory, Upton, NY 11973-5000**

The Fermi liquid theory of the normal state and the BCS-Eliashberg theory of the superconducting state were not designed for doped correlated insulators, such as the high temperature superconductors. Thus it is necessary to develop new theoretical ideas to understand the properties of these materials. Since the motion of a single hole in an antiferromagnet is frustrated, it is argued that the driving force for the physics of a finite concentration of doped holes is the need to reduce their zero-point kinetic energy. This proceeds in three steps that are reflected in a sequence of crossovers and phase transitions, which constitute a new mechanism and many-body theory of superconductivity. First of all, the system develops a charge-inhomogeneous state – an array of metallic stripes that forms an electronic liquid crystal; this lowers the kinetic energy along a stripe. In the transverse direction in the CuO_2 planes, the kinetic energy is lowered by pair hopping, which first creates spin pairs and then, at a lower temperature, superconducting phase coherence. The predictions of electronic inhomogeneity and the presence of pairing correlations above T_c have been confirmed experimentally.

LC35 4 Density Matrix Renormalization Group Studies of Stripes in the t-J model.
STEVEN R. WHITE, *UC Irvine*

Using the density matrix renormalization group, we have studied the 2D t-J model at various dopings on clusters as large as 19x8. We find that the formation of stripes or stripe-like structures is a generic phenomena. For a doping of x=1/8, we find a striped pattern of half-filled walls which is consistent with neutron scattering on $LaNdSrCuO_4$. By analyzing the energetics of a single domain wall, and the interactions between walls, we find that for $x < 1/8$, the system has (1,0) half-filled domain walls, while for $1/8 < x < 1/6$, the system has a possibly phase-separated mixture of half-filled and filled walls. For $x > 0.17$, there are only filled walls. These results are consistent with neutron scattering by Yamada, et. al. provided that one assumes that the peak from the filled walls is much weaker than the peak from the half-filled walls, and consequently was not seen. Or results suggest a much greater tendency for fluctuations in the filled walls, which supports this hypothesis. We also find the possibility of domain wall loops at very low doping. We also report on the effects of next nearest neighbor hopping on stripe stability and pairing. See Steven R. White and D.J. Scalapino, Phys. Rev. Lett. 80, 1272 (1998); Phys. Rev. Lett. 81, 3227 (1998).

SESSION LC36: NONLINEAR MAGNETIC EXCITATIONS: SOLITONS, INSTABILITIES AND CHAOS
Tuesday afternoon, 23 March 1999; Room 158W GWCC at 13:15; Andrei Slavin, Oakland University, presiding

Invited Paper

13:15
LC36 1 Generation, propagation, and amplification of microwave magnetic envelope solitons in ferrite films.*
CARL E. PATTON, *Department of Physics, Colorado State University, Fort Collins, CO 80523 USA*

Envelope solitons are of interest from the perspective of basic nonlinear physics and for applications in signal processing and communications. There is a growing interest in microwave solitons in magnetic thin films for such studies and applications. Both bright and dark microwave magnetic envelope (MME) solitons have been generated from nonlinear spin-wave packets in yttrium iron garnet thin films. Envelope soliton behavior is evident from the time resolved wave forms observed for various input power and pulse width combinations, from output vs input power profiles, and from measurements of the decay, collision, phase, and velocity properties of these excitations. Numerical modeling based on the nonlinear Schrödinger equation yields pulse shapes and peak power response curves which match experiment if careful attention is given to initial conditions, accurate parameters, and spin wave band edge filtering. Parametric pumping processes have been used to amplify propagating MME solitons and to boost lower power MME pulses to

soliton status. Active feedback techniques have been used to produce decay free soliton trains, to generate bright surface wave and dark backward volume wave solitons under conditions for which the Lighthill criterion is not usually satisfied, and to form fundamental dark solitons with the predicted one hundred and eighty degree phase shift across the pulse. This work has been supported by the U. S. Army Research Office, Grants DAAH04-95-1-0325 and DAAG55-98-1-0430, the National Science Foundation, Grants DMR-9400276 and DMR-9801649, the North Atlantic Treaty Organization (NATO), Linkage Grants HTECH.LG 931489 and HTECH.LG.970538, and the Office of Naval Research, Grant N00014-91-J-1324.

GRIMALSKY, YU. RAPOPORT, *T.S. Kiev State University, 252601 Kiev, Ukraine* A.N. SLAVIN, *Dept. of Physics, Oakland University, Rochester, MI-48309, USA*‖ We have studied the propagation and the collision of microwave-excited, nonlinear spin wave packets of magnetostatic backward volume modes in ferrite films using a newly developed space- and time-resolved Brillouin light scattering technique. In narrow, quasi-one-dimensional samples we have investigated the process of formation and propagation of envelope solitons. In wide samples, corresponding to the two-dimensional case, we observe simultaneous self-focusing of a moving wave pulse in two spatial directions, and formation of strongly localized quasi-stable spin wave packets (spin wave "bullets"), collapse of which is stopped by dissipation. Collision experiments reveal, that envelope solitons retain their shape after collision. In sharp contrast, collision of spin wave "bullets" leads to their destruction by collapse in the collision region. The experimental results are in good qualitative agreement with numerical simulations.

LC36 3 Spatiotemporal Chaos in Yttrium Iron Garnet Films C.L. GOODRIDGE, *Naval Research Laboratory* T. L. CARROLL, L. M. PECORA, F. J. RACHFORD, *Naval Research Laboratory** The nonlinear behavior of magnetostatic wave states in thin films of Yttrium Iron Garnet is experimentally studied. Chaotic spin wave states result when these films are excited at resonant frequencies (2-4 GHz) and various spin wave modes begin to interact. The samples (10-37 μm thick rectangular or circular films) are placed in a strong DC field to align the spins, which are then excited using patterned slotlines, patterned coplanar waveguides, or conducting loops. We use two experimental systems to study the spatial correlation of the chaotic state of the sample. In one experiment, we use two coplanar slotline probes to simultaneously measure the magnetic state at two different positions on the sample. In the second experiment, we use an optical system consisting of two laser beams to achieve improved resolution. The magnetic state is determined by monitoring the Faraday rotation of the beams in this case.

LC36 4 Bifurcation to chaos as a method to design and implement techniques for controlling chaos in auto-oscillations in circular YIG films. NIKOLAY PISKUN, *The Ohio State University* PHILIP WIGEN, *The Ohio State University* In order to better understand the nonlinear behavior in magnetic systems an experimental and numerical study of bifurcation to chaos in auto-oscillations is presented. Experiments have been performed with thin circular yttrium iron garnet (YIG) films using perpendicular high-power ferromagnetic resonance. Taking the magnetic field as a variable parameter the bifurcation route to chaos has been investigated. Along with the modeled signal, the time dependence of complex Lyapunov exponents has been investigated. The numerical analysis is based on six coupled equations of motion for three complex magneto-static modes. It has been found that during one trajectory cycle one of the three complex conjugate Lyapunov exponent pairs undergoes the transformation into the pair of two real distinct solutions one of which quickly goes above zero. The corresponding imaginary parts are equal to zero over this time range. It is during this period when period the real exponents of the system are positive and modifying its periodic orbit the system dramatically changes its behavior, thus spanning through the whole attractor of the nonlinear system. Thus it has been demonstrated how by applying a small periodic perturbation it is possible to destroy this Lyapunov pair breaking and effectively control chaotic system.

14:27

LC36 5 Brillouin scattering from microwave magnetic solitons in thin films H. XIA, P. KABOS, H. Y. ZHANG, P. KOLODIN, C. E. PATTON, *Department of Physics, The Colorado State University, Fort Collins, CO 80523* First Brillouin light scattering (BLS) has been used to measure magnon distributions of microwave magnetic envelope (MME) solitons in yttrium iron garnet thin films. The experiments were done in the magnetostatic backward volume wave (MSBVW) configuration. The MME pulses were excited by 5 GHz, 14 ns wide pulses applied to a 50 μm wide microstrip transducer. The frequency selective multi-pass, tandem BLS spectrometer and a special diaphragm arrangement allowed for the selective detection of the magnon wave number km out to 1.3×10^4 rad/cm, as well as the wave vector k_m angle distributions. At moderate powers for which single soliton pulses were excited, the BLS data revealed (i) spin waves directly associated with the solitons with k_m-values in the $\pm$ 300 rad/cm range and (ii) additional spin waves in the 1000-2500 rad/cm range associated with other MSBVW modes excited by the antenna. At high powers for which multisoliton processes occur, the BLS data showed high k_m spin waves in the 2500-5000 rad/cm range with discrete in-plane k_m directions at 90^o and other angles around 90^o relative to the MME pulse propagation direction. These high

k_m spin waves provide the first direct evidence of spin wave shedding associated with solitons at high powers.

LC36 6 Generation of Dark Spin-Wave-Envelope Solitons in Magnetic Films YURI S. KIVSHAR,* *Optical Sciences Centre, The Australian National University, Canberra ACT 0200, Australia* ANDREI N. SLAVIN,† *Oakland University, Rochester, MI-48309* ELENA A. OSTROVSKAYA, *Optical Sciences Centre, ANU, Australia* HARTMUT BENNER,‡ *Technische Universität Darmstadt, D-64289 Darmstadt, Germany* We present a theory of dark spin-wave-envelope soliton generation in ferrite films. We show that, in the process of spin wave excitation, an input electromagnetic pulse with no intentional phase modulation undergoes a nonlinear phase shift, so that the initial spin wave generated in the film acquires a spatial phase shift inversely proportional to the square of the wave group velocity. Using the formalism of the inverse scattering transform for an input rectangular pulse with a nonlinearity-induced spatial phase shift, we predict generation of any (odd or even) number of dark envelope solitons by varying the pulse intensity only, thereby providing a theoretical explanation of experimental results.

LC36 7 Phase Conjugation and Wave Front Reversal of Spin Wave Pulses in Magnetic Films A.N. SLAVIN, *Department of Physics, Oakland University, Rochester, Michigan** G.A. MELKOV, A.A. SERGA, V.S. TIBERKEVICH, A.N. OLIYNYK, A.V. BAGADA, *Radiophysics Faculty, Taras Shevchenko Kiev State University, Kiev, Ukraine*† The effects of phase conjugation and wave front reversal have been observed for the first time for short pulses of dipolar spin waves propagating in tangentially magnetized yttrium-iron garnet films. The spin wave pulse with conjugated phase and reversed front was formed as a result of a first-order parametric interaction of the input signal pulse with non-stationary (pulsed) longitudinal microwave pumping localized in the region of the length L= 0.2 mm along the path of signal pulse propagation. The pulsed pumping field was created by a strip-line microwave resonator situated between the input and output microstrip transducers. The carrier frequency of the signal pulse was 4.67 GHz, while the pumping frequency was twice as large. The problem of parametric interaction between an input wave pulse and a non-stationary localized pumping field was solved analytically using Green's functions formalism, and gave a good quantitative explanation of the observed phenomena.

LC36 8 Instability of antiferromagnetic magnons in strong fields MICHAEL ZHITOMIRSKY, *Theoretische Physik, ETH-Hönggeberg, Zürich* ALEXANDER CHERNYSHEV, *Physics Department, University of California, Riverside* We show that spin-waves in an ordered quantum antiferromagnet in a strong magnetic field become unstable with respect to spontaneous two-magnon decays.[1] At zero temperature, the instability occurs between the threshold field H^* and the saturation field H_c. We calculate consequences of this effect on spin dynamics for two- and three-dimensional systems. The single-magnon excitations at high fields are overdamped and disappear in the most part of the Brillouin zone.

LC36 9 Radio Frequency impedance of magnetic microwires and multilayers* H. SRIKANTH, J. WIGGINS, K.-Y. WANG, *Advanced Materials Research Institute(AMRI), University of New Orleans* J. TANG, *AMRI and Physics Dept.,University of New Orleans* J.Q. WANG, C. J. O'CONNOR, *AMRI, University of New Orleans*† The radio frequency (RF) electrodynamic response is a very sensitive probe of charge and spin dynamics in magnetic materials. Dynamic experiments are well suited to study the electronic and magnetic scattering effects in systems exhibiting Giant Magnetoresistance (GMR) like multilayers and soft ferromagnetic wires. We report complex impedance ($Z(\omega,H,T)$) measurements of glass-coated Fe-Ni-Cu microwires prepared by Taylor's technique and granular Cu/Co multilayers exhibiting GMR. The measurements are done using two different techniques. $Z(\omega,H,T)$ is measured over a frequency range from 0 to 200MHz using an RF lock-in amplifier and a customized low temperature probe with co-axial cables that operates with a Quantum Design PPMS. The temperature and DC field can be varied from 1.9K to 350K and 0 to 9T, respectively. The second technique is based on a very sensitive tunnel-diode oscillator (TDO)resonant method operating at a frequency around 5MHz. Systematic magneto-impedance results and analysis for the microwire and multilayer samples and comparison with conventional GMR will be presented.

LC36 10 Magnetic Microwave Envelope Solitons in the Model with Nonlinear Dispersion* CRAIG E. ZASPEL, *Western Montana College, Dillon, MT 59725* Microwave magnetic envelope solitons in a thin film can be modeled by a higher order nonlinear Schroedinger (HONLS) equation containing nonlinear as well as third order dispersived terms. We have obtained an exact bright soliton solution of the HONLS equation, which has the same sech form as the solution of the standard nonlinear Schroedinger (NLS) equation. There are, however, significant differences between the solutions. First, the HONLS solution is chirped with a carrier wave phase shift across the pulse. Second, the HONLS solution has an amplitude-dependent velocity, but the NLS soliton velocity is an independent parameter. This new solution thereby provides two methods by which experimenters can determine whether the NLS or the HONLS equation models bright solitons in thin films.

LC37 1 Time Reversal Symmetry Breaking in the Superconducting State of Sr_2RuO_4.
GRAEME M. LUKE, *Dept. of Physics & Astronomy, McMaster University, Hamilton, Ontario, Canada L8P 4M1.*

Sr_2RuO_4 has received a great deal of recent interest due to the likelihood that it is an unconventional superconductor (*ie.* its superconducting state breaks more than U(1) gauge symmetry). We have performed[1] zero field muon spin relaxation (ZF–μSR) measurements of several single crystals with T_c ranging from 1.0 K to 1.45 K. We observe a spontaneous magnetic field which appears at T_c, demonstrating that the superconducting state in Sr_2RuO_4 is characterized by broken time reversal symmetry. This observation, combined with a consideration of the crystal symmetry indicates that its superconductivity is of p-wave (odd-parity) type, analagous to superfluid ^{3}He. In transverse field precession (TF–μSR) measurements we observe a magnetic field distribution characteristic of a square flux line lattice at all fields studied. Fitting our data to the theory of Agterberg we find that the penetration depth $\lambda(T \rightarrow 0) \approx 1900$ Åand the coherence length $\xi(T \rightarrow 0) \approx 760$ Å.

LC37 2 Flux Line Lattice in Sr_2RuO_4.*
E.M. (TED) FORGAN,† *School of Physics and Astronomy, University of Birmingham, B15 2TT, U.K.*

By small-angle neutron scattering measurements in the mixed state of strontium ruthenate, we observe that the magnetic flux lines form a square lattice over a wide range of fields and temperatures. By comparing derived values of lambda and xi with those calculated from Fermi surface properties, we show that essentially ''single-band'' superconductivity occurs in this material. The symmetry and orientation of the flux line lattice, and the values of the superconducting parameters all indicate that superconductivity occurs primarily on the gamma sheet of the Fermi surface. The p-wave ''orbital-dependent superconductivity'' scenario of Agterberg, Rice and Sigrist gives the most consistent explanation of our results as a whole.

LC37 3 Orbital Dependent Ferromagnetic Correlations in Sr_2RuO_4 from ^{17}O NMR.*
TAKASHI IMAI, *Dept. of Physics and Center for Materials Science and Engineering, MIT*

We carried out ^{17}O and ^{101}Ru NMR in Sr_2RuO_4 up to 500 K using ^{17}O isotope enriched single crystals, and probed the unconventional metallic state above T_c (= 1 K).[1] Identical temperature dependence of ^{17}O and ^{101}Ru nuclear spin-lattice relaxation rates $^{17}1/T_1$ and $^{101}1/T_1$ establishes that spin correlations are predominantly ferromagnetic in origin. Growth of $^{17,101}1/T_1T$ slows down at $T^* = 80$ K where c-axis charge transport gains coherence. $^{17,101}1/T_1T$ saturates below $T_{FL} = 25$ K in the canonocal Fermi liquid state. Comparison of ^{17}O and ^{101}Ru NMR Knight shifts along three orthogonal directions indicates that there is more than one independent component in the temperature dependence of the uniform spin susceptibilty χ. Utilizing the direction dependence of the dipole hyperfine fields from O 2p(π) orbitals, we separate χ_{xy} and $\chi_{yz,zx}$, the contributions from the Ru $4d_{xy}$ and $4d_{yz,zx}$ orbitals, respectively. We will compare the present results with ^{17}O NMR data measured for a related itinerant ferromagnet $(Sr_{1-x}Ca_x)RuO_3$.[2]

LC37 4 p-Wave Superconductivity in Sr_2RuO_4.
DANIEL F. AGTERBERG, *NHMFL*

There now exists a considerable amount of experimental evidence that Sr_2RuO_4 is a p-wave superconductor. In this talk the theoretical basis for understanding the observed properties will be discussed. A largely model independent microscopic theory (orbital dependent superconductivity) in which it is shown that the superconductivity in this system behaves

as two nearly independent subsystems will be presented. This will be followed by an examination of the phenomenological theory with an emphasis on the vortex lattice phase diagram. It will be argued that all the experimental observations are consistent with a superconducting state that is the two-dimensional analogue of the A-phase of superfluid ^{3}He and with the pairing taking place only in the portion of the Fermi surface that stems from the $Ru^{4+}xy$ orbitals.

LC38 1 New Application of Finite Size Scaling to Spin Glasses* MATTEO PALASSINI, *Physics Department, University of California, Santa Cruz, CA 95064* Finite size scaling (FSS) is a powerful tool in the study of phase transitions. Here, an alternative FSS method is used to investigate the spin glass transition in two– and three–dimensional Ising spin glasses (with $\pm J$ interactions). In this approach, universal FSS functions are determined from Monte Carlo simulations and are used to iteratively extrapolate finite–volume data to infinite volume. Large values of the bulk correlation length ξ can be reached in this way, which allows us to determine the ordering temperature and the critical exponents ν and γ from the behavior of the bulk observables. The main advantages of this approach are that no ansatz for the divergence of ξ (*i.e.* exponential or power law) is needed, and that simulations require only small sizes. Our results for two and three dimensions will be discussed in detail.

13:27
LC38 2 A Hard-Spin Mean-Field Study of the Three-Dimensional Ising Spin Glass in a Magnetic Field VRISHALI JAVERI, SUSAN R. McKAY, *Department of Physics and Astronomy, U. of Maine, Orono, Maine 04469-5709* We have tracked the evolution of the distribution of local magnetizations as a function of magnetic field H, using Monte Carlo hard-spin mean-field theory[1] applied to the Ising spin glass. Even at H/J $\approx$ 1, the distribution of local magnetizations remains bimodal and the overlap with the H=0 ground state is significant. The overlap and magnetization curves, as H is increased from zero at fixed low temperature, show a step-like structure which is not seen in temperature scans at fixed (or zero) field. Calculated overlaps indicate the presence of highly degenerate low-energy states in both zero and low field cases.

13:39
LC38 3 Evidence for the droplet theory of spin glasses MIKE MOORE, *University of Manchester* HEMANT BOKIL, *University of Manchester* BARBARA DROSSEL, *University of Manchester* We have studied the Parisi overlap distribution for the three-dimensional Ising spin glass in the Migdal-Kadanoff approximation. For temperatures $T \simeq 0.7T_c$ and system sizes up to $L = 32$, we found a $P(q)$ as expected for full Parisi replica symmetry breaking, just as was also observed in recent Monte Carlo simulations on a cubic lattice. However, for lower temperatures our data agree with predictions from the droplet or scaling picture. The failure to see droplet model behavior in Monte Carlo simulations is due to the fact that all existing simulations have been done at temperatures too close to the transition temperature so that system sizes larger than the correlation length have not been achieved.

13:51
LC38 4 Bivariate Multicanonical Monte Carlo of the 3D $\pm J$ Spin Glass* HATANO NAOMICHI, JAMES E. GUBERNATIS, *Theoretical Division, Los Alamos National Laboratory* A bivariate multicanonical Monte Carlo simulation of the three-dimensional $\pm J$ spin glass is described. The autocorrelation time of this method is approximately proportional to the system size, which is a great improvement over previous methods. Preliminary results of the simulation show the following: (1) There is a clear crossing point in the Binder-parameter plot at $T_c \simeq 1.3$. This suggests that many previous simulations, where the crossing either did not exist or was subtle, might have underestimated the spin-glass order at low temperatures. (2) The order-parameter distribution $P(q)$ at $q = 0$ and $T = 0.3$ appears to decrease as the system size is increased. This is an indication of the droplet picture for the low-temperature phase. On the other hand, the estimate of $P(0)$ at $T = 0.7$ does not appear to decrease as the system size is increased. This suggests that $T = 0.7$ is outside the scaling region of the zero-temperature fixed point.

LC38 6 Exchange Interaction and Spin Glass Properties of Two-Dimensional Localized Electrons* A. L. EFROS, *University of Utah* V. V. FLAMBAUM, I. V. PONOMAREV, *University of New South Wales, Sydney 2052, Australia* The problem of exchange interaction of two electrons localized by the potential of charged donors is solved analytically. The energy difference between triplet and singlet is obtained as a function of the lateral distance between the donors and of the vertical separations of the donors from the plane with the two-dimensional electrons. The singlet-triplet splitting has been found to be a very sharp function of a lateral distance. This gives a clue to the structure of the many-particle state. For randomly distributed donors the nearest neighbors form singlet states which interact very weak with the

other spins. Thus, the hierarchy of interaction scales appears in the problem. The low-temperature distribution of effective fields is discussed. The exchange interaction may cause a specific magnetoresistance if the magnetic field is parallel to the plane.

14:27

LC38 7 Landau Theory of Bi-criticality in a Random Quantum Rotor System DENIS DALIDOVICH, *University of Illinois at Urbana-Champaign* PHILIP PHILLIPS, *University of Illinois at Urbana-Champaign* We consider here a generalization of the random quantum rotor model in which each rotor is characterized by an M-component vector spin. We focus entirely on the case not considered previously, namely when the distribution of exchange interactions has non-zero mean. Inclusion of non-zero mean permits a ferromagnetic and superconducting phases for $M = 1$ and $M = 2$, respectively. We find that quite generally, the Landau theory for this system can be recast as a zero-mean problem in the presence of a magnetic field. Naturally then, we find that a Gabay-Toulouse line exists for $M > 1$ when the distribution of exchange interactions has non-zero mean. The solution to the saddle point equations is presented in the vicinity of the bi-critical point characterized by the intersection of the ferromagnetic (M=1) or superconducting (M=2) phase with the paramagnetic and spin glass phases. All transitions are observed to be second order. At zero temperature, we find that the ferromagnetic order parameter is non-analytic in the parameter that controls the paramagnet/ferromagnet transition in the absence of disorder. Also for M=1, we find that replica symmetry breaking is present but vanishes at low temperatures.

14:39

LC38 8 Instantons in the Langevin dynamics. Applications to spin glasses. ANDREI LOPATIN, *Rutgers University* LEV IOFFE, *Rutgers University* We consider the application of the Langevin dynamics to rare processes like transitions between metastable states in the spin glasses. These processes can be described by instantons in the Lagrangian approach to the Langevin dynamics. We show that an instanton (uphill) process can be mapped into a usual (downhill) process going back in time. We apply this method to the spherical SK and p-spin interaction spin-glass models and find the probabilities of transitions between the metastable states.

14:51

LC38 9 Numerical Simulations of the Random Bond q-state Potts Model TERRY OLSON, *University of California, Santa Cruz* A. P. YOUNG, *University of California, Santa Cruz* We study the critical behavior of the random bond q-state Potts model by using a Monte Carlo cluster algorithm. Rather than the usual self-dual *binary* distribution of interactions, we use a distribution which is *continuous* as well as self-dual. We find that spin-spin correlation functions at the critical point have very broad distributions, so the critical exponent η, which describes the power law decay of correlations at criticality, is not unique but depends on which moment is considered. This is in agreement with analytical theory. For the first time, we obtain the value of η for the *typical* correlation function (obtained from the average of the log) for a range of q-values. Our results for η for the average correlation function are in slight disagreement with earlier work. We discuss possible reasons for this discrepancy.

15:03

LC38 10 Hysteresis, frustration, and self-organized criticality in random magnets FERENC PÁZMÁNDI, *Kossuth University, Debrecen, Hungary* GERGELY ZARÁND, GERGELY ZIMÁNYI, *University of California, Davis* ATTILA VIROSZTEK, *Technical University of Budapest, Hungary* The dipolar interaction of magnetic moments, though negligible on atomic distances, affects hysteretic processes in two important ways: the long-range forces change the domain-wall motion and the antiferromagnetic coupling of parallel domains introduces frustration. We model these effects on the mean-field level with the zero-temperature Sherrington-Kirkpatrick Ising spin glass. Numerical simulations and scaling arguments suggest that the avalanche-size distributions obey power laws characterized by a new set of exponents. We find large avalanches and self-organized criticality everywhere in the hysteresis loop. We propose an analytic description of the system in terms of locally stable states.

15:15

LC38 11 Dynamical hierarchies can give quantitative agreement with the equilibrium and aging behavior of $Cu_{0.9}Mn_{0.1}$ P. W. FENIMORE, M. B. WEISSMAN, *University of Illinois at Urbana-Champaign* Using simulations, we demonstrate that there exist parameters for which hierarchical dynamics on a tree of accessible states can quantitatively reproduce both the 4-point equilibrium fluctuation statistics (the second spectrum) and the $\ln(t)$ aging of the dynamical susceptibility observed in $Cu_{0.9}Mn_{0.1}$. In the equilibrium case the simulation reproduces the magnitude, smoothness and exponent of the second spectrum. In the non-equilibrium case, the magnitude of the aging is correctly reproduced. The tree of accessible states is closely related to previous dynamical models of spin glasses[1]. The essential feature of our model is a *truncated* exponential distribution of randomized trapping energies.

[1]A. T. Ogielski, D. L. Stein, Phys. Rev. Lett. **55**, 1634 (1985) and J.-P. Bouchaud, D. S. Dean, J. Phys. France I **5** 265 (1995).

LC38 12 Lightly Doped Diluted Magnetic Semiconductors: An Unusual Ferromagnet* R. N. BHATT, *Department of Electrical Engineering, Princeton University, Princeton NJ 08544-5263* Recent investigations of diluted magnetic semiconductors such as $Zn_{1-x}Mn_xTe$ and $Cd_{1-x}Mn_xTe$ with small x (regime below the spin-glass transition) lightly doped with carriers (at concentrations below the metal-insulator transition) suggest that the system becomes ferromagnetic at low temperatures[1]. We study the properties of the ferromagnetic phase, and find them to be very different from a garden variety ferromagnet. In particular, we show that the thermodynamics in the ferromagnetic phase is dominated not by long wavelength spin fluctuations, but instead by rare fluctuations in the dopant and magnetic ion distributions.

LC41 1 A Facility for Simulating the Dynamic Response of Materials.*
DANIEL MEIRON, *Applied Mathematics, California Institute of Technology*

The Center for Simulating Dynamic Response of Materials, a DOE ASCI Center of Excellence at the California Institute of Technology, is constructing a virtual shock physics facility in which the full three-dimensional response of a variety of target materials can be computed for a wide range of compressive, tensional, and shear loadings including those loadings produced by detonation of energetic materials. The goals are to

Facilitate computation of a variety of experiments in which strong shock and detonation waves are made to impinge on targets consisting of various combinations of materials,

Compute the subsequent dynamic response of the target materials,

Validate these computations against experimental data.

The research is centered on the three primary stages required to conduct a ''virtual experiment'' in this facility: detonation of high explosives, interaction of shock waves with materials, and shock-induced compressible turbulence and mixing. The modeling requirements are addressed through five integrated research initiatives that guide the key disciplinary activities:

Modeling and simulation of fundamental processes in detonation,

Modeling dynamic response of solids,

First principles computation of materials properties,

Compressible turbulence and mixing, and

Computational and computer science infrastructure.

Of critical importance in performing a simulation of this type is the ability to bridge widely disparate length scales which realte to the dynamic response of both the explosive and the target materials. In this presentation the speaker will provide an overview of the multi-scale modeling research in progress at the center and the computational sciecne research which facilitates the simulations. Additional information on our work can be obtained by visiting our web page http://www.cacr.caltech.edu/ASAP.

LC41 2 Connecting Astrophysics to Laboratory Experiments: Astrophysical Thermonuclear Flashes.
ROBERT ROSNER, *The University of Chicago*

Our understanding of highly dynamic and nonlinear astrophysical phenomena such as transient thermonuclear burning within, or on the surface of, evolved compact stars such as white dwarfs is strongly dependent on the versimilitude of numerical simulations. Because the dynamic range of the spatial scales of such phenomena are far beyond our ability to carry out direct numerical simulations, we must rely upon modeling of the sub-gridscale physics; similarly, we need to develop approximation schemes that allow us to overcome the limitations imposed by the enormous dynamic range of the temporal behavior. It is then extremely important to test the versimilitude of our calculations, independent of the astrophysical observations we seek to understand; this has led us to use laboratory fluid dynamical experiments as test beds for our calculations.

14:27
LC41 3 Large-Scale Quantum Monte Carlo Simulations of Correlated Electron Systems.
CAREY HUSCROFT, *University of Cincinnati*

Quantum Monte Carlo (QMC) is an exact numerical technique for calculating quantities such as charge and spin correlations, densities of states, and thermodynamic properties in quantum systems. QMC has been used successfully to gain insight into the physics of many systems, but its great computational expense has limited its applicability. Using recently available large-scale computational resources, we can now address formerly intractable problems with QMC. An example is the f-electron correlation driven phase transition under pressure, seen in a number of rare-earth metals and

characterized by large (5–15%) volume changes. In the high-pressure regime, approximate techniques give a good description of the material structure. However, exact treatments of correlations are needed to reproduce the transition and the low-pressure, strongly correlated phase. While exact, full-orbital approaches are still beyond reach, using large-scale QMC one can obtain exact solutions of appropriate models, such as the two-band Periodic Anderson Model, and obtain considerable insight into the nature of such transitions.

15:03
LC41 4 Large Scale Ab Initio Molecular Dynamics Simulations in Materials Science.*
FRANCOIS GYGI, *Lawrence Livermore National Laboratory, Livermore CA 94551.*†

Ab initio molecular dynamics has a history of applications to numerous problems in solid state physics, chemistry and, more recently, biochemistry. The advent of large scale computing facilities is now extending the domain of application of this technique to ever more complex systems. The ability to extend simulation sizes to several hundred atoms, for durations of tens of picoseconds allows to study new problems such as the behaviour of complex liquids under pressure, the solvation properties of biomolecules, or microfracture in complex solids. We will discuss the results of ab initio MD simulations carried out on the recently installed ASCI platforms at LLNL. The new challenges implied by the unprecendented scale of these calculations will also be described.

*Work done in collaboration with G.Galli and F.Ree, LLNL.

13:15
LC42 1 Spanning clusters in critical percolation. Finite size scaling. LEV SHCHUR, *Landau Institute for Theoretical Physics, 142432 Chernogolovka, Russia* SERGEY KOSYAKOV, *Landau Institute for Theoretical Physics, 142432 Chernogolovka, Russia* Probabilities of spanning clusters in critical site percolation are computed. Square and cubic lattices with the free and periodic boundaries and with different aspect ratios are investigated. Finite size scaling of probabilities were discussed. Finally, the detailed comparison with the existing analytical results are discussed.

13:27
LC42 2 Aspects of Universality in Percolation ROBERT ZIFF, CHRISTIAN LORENZ, *University of Michigan* PETER KLEBAN, *University of Maine* Besides the familiar universality of critical exponents and scaling functions near the critical point, the phenomenon of universality is evident in many additional aspects of percolation. For finite systems precisely at the (infinite-system) critical threshold, there exist numerous shape-dependent universal properties, such as the excess cluster number, cross-configuration probability, and certain amplitude ratios. These quantities also depend upon boudary conditions, including the twist in the boundary when periodic b.c.'s are used. (They are still considered universal because they do not depend upon the underlying model or lattice that is used.) Explicit expressions for a torus with a twist are derived. The infinite-system size distribution $n_s \sim s^{-tau}$ can be reformulated into a universal form by stating that the number of clusters whose $x -$ or $y -$ dimension is greater than a length L, per unit area L^2, is a constant (0.116). The universality of the corrections-to-scaling exponent is also discussed.

13:39
LC42 3 Static and dynamic critical behaviors of fully coordinated percolation EDUARDO CUANSING, JAE HWA KIM, HISAO NAKANISHI, *Purdue University* We study the static and dynamic critical behaviors of the fully coordinated percolation clusters on the square lattice. Fully coordinated percolation refers to the geometrical phase transition of the connectivity among the sites all of whose neighbors are occupied. Our preliminary results from Monte Carlo simulations (static exponents) and normal mode analyses (dynamic exponents) suggest that this problem is in the same universality class with ordinary percolation *statically* but not so *dynamically*. This may be attributable to the local correlations introduced by the full coordination requirements, somewhat similar to loopless or loop-enhanced percolation problems.[1] We also present a *breadth first* Monte Carlo algorithm to implement the full coordination statistics simultaneously as the percolation cluster is grown in simulation.

13:51
LC42 4 Ordering in a High-q Antiferromagnetic Potts Model on a Simple Cubic Lattice SHAFIQUR RAHMAN, *Allegheny College, Meadville, PA 16335* We have investigated the ordering in four-, five- and six-state antiferromagnetic Potts models on a simple cubic lattice by using an efficient cluster flipping Monte-Carlo algorithm(1). Unlike the q=3 case(2), which moves from a broken-sublattice-symmetry state to a rotationally-symmetric state before reaching the paramagnetic transition as temperature is increased, the higher q-states show much simpler behavior. For the q=4 case, we find that at small temperatures, two of the states are distributed randomly on one sublattice while the other two are distributed randomly on the other sublattice. The system undergoes a transition to the paramagnetic state at a finite temperature. For the q=5 case, the transition to the paramagnetic state appears to be at T=0. The q=6 case is currently under investigation. Preliminary results show no transition at finite temperature. 1 R. H. Swendsen and J.-S. Wang, Phys. Rev. Lett. 58, 86 (1987). 2 S. Rahman, E. Rush and R.H.Swendsen, Phys. Rev. B 58, 9125 (1998).

LC42 5 Phase transitions in the q=5 state Potts model in an uniform external magnetic field. NILAY ROY, *Center for Simulational Physics, University of Georgia, Athens, Georgia.* DAVID LANDAU, *Center for Simulational Physics, University of Georgia, Athens, Georgia.* The q=5 state ferromagnetic Potts Model in d=2 dimensions has been the focus of investigation for many years. There has been no attempt yet to fully understand the phase behaviour of this model in the entire space of positive and negative uniform external magnetic field which couples to only one of the states. In the absence of a magnetic field there is known to be a weak first order transition. However the nature of transitions in a magnetic field is still unclear. We use a hybrid Metropolis-Cluster algorithm with techniques of reweighting and finite size scaling including the Lee-Kosterlitz method to determine the location of the phase boundary for both positive and negative fields. These results are compared to that obtained using a third order variational cumulant expansion technique.

14:15

LC42 6 Effects of quenched disorder in the two-dimensional Potts model RICARDO PAREDES V., *IVIC, Venezuela* JOHNNY VALBUENA, *PDVSA, Intevep* Motivated by recent experiments on phase behavior of systems confined in porous media, we have studied the effect of randomness on the nature of the phase transition in the two dimensional Potts model. To model the effects of the porous matrix we introduce a random distribution of couplings, $\mathcal{P}(J_{ij}) = p\,\delta(J_{ij} - J_1) + (1 - p)\delta(J_{ij} - J_2)$, in the q state Potts Hamiltonian. An extensive Monte Carlo study is made on this system for $q = 5$. We studied two different cases of disorder (a) $J_1/J_2 \to \infty$ and $p = 0.8$ and (b) $J_1/J_2 = 10$ and $p = 0.5$. We observed, in both cases, that the weak first order transition that appears in the pure case, changes two a second order transition. A finite size scaling analysis shows that, the correlation length exponent, ν is close to 1 and the best fit to the dependence of the specific heat on system size is logarithmic. This suggests that both cases belong to the universality class of the Ising model. In contrast, the magnetic exponents point to a different universality class.

14:27

LC42 7 Critical dynamics of Heisenberg antiferromagnets: simulation versus theory and experiment SHAN-HO TSAI, ALEX BUNKER, D. P. LANDAU, *Center for Simulational Physics, The University of Georgia, Athens, GA 30602 USA* We use spin-dynamics techniques to perform large-scale simulations of the dynamic behavior of the classical Heisenberg antiferromagnet in three dimensions. Time-evolutions of spin configurations are determined numerically from coupled equations of motion for individual spins using a new algorithm[1] based on Suzuki-Trotter decompositions of exponential operators. The dynamic structure factor is calculated from the space- and time-displaced spin-spin correlation function. We study the width of spin-wave peaks as a function of the wave-vector for temperature below but close to the critical value. Our results are compared with some theoretical predictions which in turn disagree with very recent experimental results. Our preliminary data indicate that hydrodynamic theory only holds for wave-vectors which are far from the Brillouin zone boundary.

14:39

LC42 8 Nonequilibrium relaxation of the 3dim ± J EA model FUGAO WANG, *Center for Simulational Physics, University of Georgia, Athens, GA30602* By studying correlation functions of two replicas with the damage spreading method, we estimate the spin glass transition temperature of the 3D ± J EA model using Campbell's criterion $D(T_g, t \to \infty) = 1/2$ or $q_d^{AB}(T_g, t \to \infty) = 0$, where D and q_d^{AB} are the Hamming distance and the overlap of the two replicas, respectively. The two replicas evolve with the same sequence of the random numbers and with initial spin-configurations related to each other by $S_i^A(t = 0) = -S_i^B(t = 0)$ (for all i). From our simulational data for system sizes up to $L = 64$, the spin glass transition temperature is estimated as $T_g = 1.18 \pm 0.06$. The replica simulational method and the damage spreading method are compared with each other. The relaxation exponents of the magnetization and the correlation functions are also estimated in the vicinity of T_g on a large lattice and the dynamical critical exponent z is estimated as $z \simeq 6.0$.[0.2cm]

14:51

LC42 9 Monte Carlo study of phase separation in $Si_{1-x}Ge_x$ with the Stillinger-Weber potential JOHN LEES, D. P. LANDAU, *Center for Simulational Physics, University of Georgia* We investigate the structural properties of silicon-germanium binary alloys using Monte Carlo simulations. We employ the Stillinger-Weber model[1] at constant pressure allowing lattice vibrations in the canonical ensemble. In the model, we use a *LxLxL* box with a distortable lattice where the box volume fluctuates under constant pressure. Atoms are allowed to attempt small moves off-lattice and exchange position with a nearest neighbor atom of unlike type using Metropolis rejection criteria. We study the phase separation of the binary mixture into Si-rich and Ge-rich domains in the two-phase coexistence region. The structure factor is obtained under different temperatures and concentrations of the constituents. We then compare those results to those obtained for the rigid lattice model.

15:03

LC42 10 High-precision Monte Carlo study of the 3D XY model PETER OLSSON, *Umeå University, Sweden* The 3D XY model with spin interaction of the Villain type is studied by means of extensive Monte Carlo simulations. The critical behavior is extracted by finite size scaling analysis with corrections to scaling of the fourth-order cumulant for system sizes 8^3 through 64^3. The benefit from the study is twofold. First, a systematic way to perform this kind of analyses is suggested. This includes ideas on how to decide which data should be used in the attempted data collapse. Second, the critical temperature as well as the universal values for the exponents and the fourth-order cumulant at criticality are obtained with high precision.

Supplementary Paper

LC42 11 Dynamical Simulation of a Phase Transition in a Model Gravitating System BRUCE MILLER, PAIGE YOUNGKINS, *Texas Christian University* We present recent developments in the study of an interacting gravitational system of concentric, spherical, mass shells. The existence of two distinct phases is predicted from mean field theory. We report the results of dynamical simulations carried out under the conditions of constant energy (microcanonical ensmble), constant temperature (canonical ensemble with energy exchange with a reservoir) and constant

chemical potential (grand canonical ensemble with both particle and energy exchange). Both simulations and theory predict that, in contrast to chemical systems, the physics of each environment is different. We describe the simulation results and compare them with the theoretical predictions.

13:15
LC43 1 High-Order Nyström Method for Solving Boundary Integral Equations* JOHN OTTUSCH, MARK STALZER, JOHN VISHER, STEPHEN WANDZURA, *HRL Laboratories, LLC* The conventional Nyström method is a simple and efficient mechanism for discretizing integral equations with non-singular kernels. With a high-order quadrature rule, the solution one obtains by this method is a high-order approximation to the exact solution. We have adapted the Nyström method to handle singular kernels (such as those obtained from a wide range of partial differential equations) without sacrificing high-order convergence, by adapting Strain's method for obtaining high-order rules for singular functions. We have implemented this method in a computer code to compute electromagnetic scattering from large, arbitrarily-shaped scatterers. Use of a high-order Nyström discretization has several advantages over more conventional approaches, including improved solution accuracy, practical solution error control, and simplicity of implementation. We will explain the method, show numerical results demonstrating its utility, and comment on other areas of computational physics where it may be applied.

LC43 2 Computer Optimization by Simulation for Data Analysis* GEORGE IOUP, JULIETTE IOUP, ABOLFAZL AMINI,[†]JAMES LECLERE,[‡] *University of New Orleans* LISA PFLUG, *Naval Research Laboratory Stennis Space Center* Transform-based signal (data) analysis is a generally neglected area of physics education, even though many physicists benefit from knowledge of this area in their work. At the University of New Orleans, two of the authors have developed a sequence of five regular and two special topics physics courses dedicated to signal analysis, which are popular among students and professional physicists and geophysicists. Related research is ongoing in theoretical and computational signal analysis. In particular, methodology has been developed using optimization by simulation to determine optimum iteration number, in the presence of noise, for iterative noise removal and deconvolution of data. This kind of analysis can influence experimental design if deconvolution is to be used as part of data reduction. Also, simulations and hypothesis testing are used to evaluate the performance of higher-order correlation based detection and time delay estimation algorithms. Results of these investigations are summarized.

LC43 3 An Object-Oriented Electric Field Propagation Model using IBM VisualAge for C++ DAVID YEVICK, *Department of Electrical and Computer Engineering, Queen's University, Kingston, Ont. K7L 3N6, Canada* We are in the process of developing a fully object-oriented model of electric field propagation in waveguiding structures within the IBM VisualAge for C++ Integrated Development Environment. Our program employs the technique of visual construction from parts combined with polymorphism through virtual function calls and abstract classes to generate uniform code that can be applied to different types of electric fields (e.g. scalar, vector, 2-dimensional or 3-dimensional) and is further very simple to modify or extend. The incorporation of Visual Builder technology allows the graphical user interface to be trivially reconfigured by any programmer to reflect program changes. We believe that our methodology can be used with advantage in wide areas of physical and mathematical modeling.

13:51
LC43 4 Beam Propagation algorithms for fast self-focusing and Solitons SUBBARAO DANTU, *Ctr. Energy Studies* UMA RAMANATHAN, *Ctr. Energy Studies* HARVINDER SINGH,* *Ctr. Energy Studies* Algorithms for beam propagation method for self-focusing and solitons based on the quasi-optic paraxial wave equation have been known for oject-oriented codes[1]. We use the full wave equation as used analytically in Ref.[2] to construct an FFT algorithm for object oriented fast soliton evolution. The various wave-forms are analysed in this situation for determining the best algorithm to chose. We also explain the possibilities and difficulties of using the more accurate harmonic oscillator basis vectors for beam propagation algorithms. [1] D. Subbarao, H. Singh , R. Uma and S. Bhaskar, Physics of Plasmas (1999, shortly appearing). [2] D. Subbarao, R. Uma and H. Singh, Physics of Plasmas, 5, 3046, (1998). *the author is presently with R& D Group, NIIT Delhi.

14:03
LC43 5 A multipole based method for simulation of magnetic systems.* MOURAD BENAKLI, *University of Alabama* PIETER VISSCHER, *University of Alabama* The study of physical problems involving long range interactions has been a challenge in computational physics for a long time, because the cost of computing the energy (or its derivatives) of a system described by N particles is proportional to N^2. Although many faster methods have been implemented to study these systems, these methods have some built-in limitations. For example, methods based on the Fast Fourier Transform (FFT), that have a computational cost proportional to $N\ln(N)$, are not suitable for non-uniform distributions of particles. The Fast Multipole Method (FMM) has a computational cost proportional to N but with a quite big coefficient ($\approx$ 10,000), making the performance breakeven point very high. We recently developed a hybrid FMM that has a very low breakeven point ($N \approx 10 - 100$) and is well suited to a non-uniform distribution of particles. We present the results of applying this method to some standard micromagnetic problems, and compare its computational cost with that of a standard FFT-based approach.

LC43 6 Integral identities for computing magnetic multipoles in small skin depth problems IGOR ZUTIC, *University of Maryland, College Park MD 20742* ORIOL T. VALLS, *University of Minnesota, Minneapolis MN 55455* Many problems in computational magnetics involve computation of fields which decay within a skin depth δ, much smaller than the sample size d. We discuss here a novel perturbation method[1] which exploits the smallness of $\epsilon \equiv \delta/d$ and the asymptotic behavior of the solution in the exterior and interior of a sample. This is achieved by formulating integral identities for magnetic multipoles which separate contributions of terms of different orders in the small parameter ϵ. To illustrate this procedure we consider the computation of the magnetic dipole and quadrupole moments of an anisotropic, unconventional, three dimensional superconductor.

[1]I. Zutic, O.T. Valls, J. Comput. Phys. **136**, 337, (1997), I.Zutic, O.T. Valls, J. Appl. Phys. **83**, 6804, (1998).

14:27

LC43 7 Acoustic Scattering in High Contrast Media* A. KOZLOFF, *Raytheon* C. THOMPSON, *UMASS Lowell* K. CHANDRA, *UMASS Lowell* V. MEHTA, *Lucent Technologies* In this work a numerical method for evaluating backscatter from a three-dimensional medium having high acoustic contrast is presented. The solution is sought in terms of a perturbation expansion in the contrast amplitude. It is shown that limitations of the regular perturbation expansion can be overcome by recasting the perturbation sequence as a rational fraction using Pade approximants. The resulting solution allow for an accurate representation of the pressure and allows for the poles in the frequency response to be modeled. The determination of the pulse-echo response for a high-contrast medium discussed and presented.

*Supported by DOE

14:39

LC43 8 Noise enhanced propagation as a numerical tool MARKUS LOCHER, *School of Physics, Georgia Institute of Technology* Recently, the phenomenon of noise enhanced propagation (NEP) was introduced in experimental settings and simulations. Here we show that in analogy to the dithering effect utilized mainly by electrical engineers, NEP can alleviate numerical artifacts resulting specifically from the discretization of spatially extended domains. Numerically observed propagation failure can be avoided, and we demonstrate that the parameter range of investigation of certain nonlinear models can be significantly extended.

14:51

LC43 9 Fekete Point Spectral Element Methods BETH WINGATE, MARK TAYLOR, *Los Alamos National Laboratory* We present a new method for the spectral finite element method on triangles (and other domains). This is a generalization of the method used on quadrilaterals (Patera 1984). We first solve a Sturm-Liouville problem on the simplex, as in Wingate and Taylor 1998, and show that the solutions of these differential equations are polynomials. We show this is a better space than the tensor product space used on quadrilaterals in the sense that the convergence of a function is faster. Next we find the Fekete points as in Taylor and Wingate 1998. Fekete points are characterized by the points which maximize the determinant of a generalized Vandermonde matrix. For the interval $[-1,1]$, with P polynomials, Fejer showed that Fekete points are the Gauss-Lobatto quadrature points. More recently Bos has shown that Fekete points in the square with P the usual diamond polynomial truncation are a tensor product of the Gauss-Lobatto quadrature points. Finally, Cardinal functions defined at Fekete points are guaranteed to have a maximum value of 1 over the domain, and thus have no wild oscillations between the points, which leads to a mass matrix condition number which grows $O(N^2)$.

15:03

LC43 10 Encryption Model Hinted from Neural Networks TORU OHIRA, Decoding of information from biological neural networks and its spike dynamics is one of the central and most difficult issues in neural network research. Complexity from nonlinearity and many-body interactions of neural networks dynamics makes this task a very challenging one to be explored. In this note, however, we reverse the question: we actually take advantage of this complexity and propose a new model of encryption motivated by neural network modelings. In particular, we take a hint from neural network models with delay. The encryption process is identified by a coupling dynamics with nonlinear threshold function and various time delays between different bits, or neurons, in the original data. We show that the model produces a complex behavior with the characteristics needed for an encryption scheme.

15:15

LC43 11 Organic Logic Elements For Novel Computer Architectures RICHARD POTEMBER, *The Johns Hopkins University, Applied Physics Laboratory, Laurel, MD 20723-6099* MIEKO MATSUZAWA, *The Johns Hopkins University, Applied Physics Laboratory, Laurel, MD 20723-6099* Content addressable memory offers significant benefits in processing speed, familiarity recognition, error correction, simplified software, and insensitivity to individual logic element failure. In an associative memory, the storage capacity increases asymptotically in relation to the number of storage elements. To fabricate dense circuitry, simply constructed logic elements are advantageous. A functional 4 bit molecular associative memory device using organic molecular materials has been demonstrated. The electrical switching and memory phenomena observed in thin films of either copper or silver complexed with the electron acceptors tetracyanoethylene (TCNE), tetracyanonapthoquinodimethane (TNAP), tetracyanoquinodimethane (TCNQ), and various TCNQ derivatives. Because the active region of the device is at molecular dimensions, the device should be scalable to a density of 10 to the fifteenth power bits per cubic centimeter. The molecular memory is capable of performing a storage function that is bistable and reversibly driven from one state to the other by an external signal.

15:27

LC43 12 Implementation of Rough Surface Electromagnetic Scattering into the Irma software code ANDY RESNICK, *Nichols Research Corporation* CHARLES J. ALBERS, JR., *Nichols Research Corporation* BRAD BLUME, *Nichols Research Corporation* An analysis of the scattering of electromagetic radiation by rough dielectric surfaces has been carried out and implemented into the Irma software code. This analysis, a second-order expansion, extends previous results carried out to first order for dielectrics and second order for perfect conductors. Irma is a

United States Air Force code designed to model air-to-ground multisensor weapons seeker systems. A requirement of the code is to produce realistic synthetic imagery derived from first principles. The recent addition of rough surface scattering is designed to more accurately model real tactical materials of interest.

LC43 13 National Transport Code Collaboration (NTCC).* A.H. KRITZ, G. BATEMAN, M. ERBA, *Lehigh U.* J. KINSEY, H. ST.JOHN, *GA* R. COHEN, R. JONG, L. LODESTRO, T. B. YANG, *LLNL* D. GREENWOOD, W. HOULBERG, *ORNL* D. McCUNE, D. MIKKELSEN, A. PLETZER, *PPPL* J. R. CARY, K. G. LUETKEMEYER, *Tech-X* J. WILEY, *U.Texas* NTCC is a multi-institutional collaboration, which is changing the way fusion modeling codes are constructed and used. Object-oriented programming (OOP) allows development of codes which are easier to use, maintain, and modify. OOP is applied to develop a Web invocable demonstration physics application with plug-in physics and solver modules, a Web-based (Java) graphical user interface, and a C++ data accessor which accesses experimental data from local files or over the Internet. These componets are connected via Common Object Request Broker Architecture (CORBA) servers. The project utilizes modules, extracted from legacy code or newly written, which have placed in a Web-based community-owned library. The modules are required to meet well defined standards. Access to the modules is facilitated by a tool, PYCFORTRAN, which generates C wrappers for Fortran subroutines and a Python interface description file. The demonstration code is used to compare the evolution electron and ion temperatures using several different transport models and experimental data from a number of Tokamaks.

MA02 1 Physics And Technology.
MARY GOOD, *Venture Capital Investors and University of Arkansas At Little Rock*

Physics is an interesting and provocative discipline. At one end of the spectrum, theoretical physics is focussed on the fundamental laws of the universe and how to explain nature in a simplified, unified way. On the other end, physics and the measurements and experiments by physicists, are the foundation of modern technology. Studies in solid state physics and the behavior of electrons in materials are the heart of semiconductor and computer technology. In today's competitive environment it is important that both of these physics thrusts continue. This presentation will focus on the role of physics in the development of technology and why it is so important to continue to educate and train young people in the discipline. The 21st century may be the century for biology but biology cannot progress without the assistance of physics and chemistry. Certainly the technology of the 21st century will still depend on the understanding that comes from searching for the fundamental phenomena that govern the universe.

DAMOP: PHOTOIONIZATION

NP01 1 Prduction of oxygen anions in the K-shell photoionization of CO W.C. STOLTE, *Univ. of Nevada, Las Vegas* D.L. HANSEN, *Univ. of Nevada, Las Vegas* H WANG, *Univ. of Nevada, Las Vegas* O.A. HEMMERS, *Univ. of Nevada, Las Vegas* D.W. LINDLE, *Univ. of Nevada, Las Vegas* I.D. LOPEZ, *Centro De Ciencias Fisicas, UNAM, Mexico* A. RIZVI, *Advanced Light Source, LBNL* A.S. SCHLACHTER, *Advanced Light Source, LBNL* M.S. LUBELL, *City College of New York* High-resolution measurements of the photofragmentation of CO in the vicinity of the C and O K edges is reported. In particular, the production of O- has been observed near both edges. Although negative ions have been seen previously in low-resolution core-hole measurements, the new results, with vibrational resolution, should be valuable for comparison to detailed spectroscopic calculations. Furthermore, there is evidence for post-collision interaction effects in cation and anion yields just above the K-edges.

NP01 2 High-Energy Valence Photoionization of Argon: Effect of Interaction with 3s Photoionization Channels* D.L. HANSEN, *Dept. of Chemistry, University of Nevada, Las Vegas* O. HEMMERS, *Dept. of Chemistry, University of Nevada, Las Vegas* H. WANG, *Dept. of Chemistry, University of Nevada, Las Vegas* D.W. LINDLE, *Dept. of Chemistry, University of Nevada, Las Vegas* H.S CHAKRABORTY, *Dept. of Physics, Indian Institute of Technology* P.C. DESHMUKH, *Dept. of Physics, Indian Institute of Technology* S.T. MANSON, *Dept. of Physics and Astronomy, Georgia State University* Electron time-of-flight measurements on argon in the photon energy range 600-850 eV were analyzed to determine the anisotropy parameter β and the ratio of the intensities of the 3p and 3s lines. Our measurements confirm the finding that the independent particle model is inadequate to explain photoionization of nl (l> 0) electrons even at energies well above the ionization threshold.

NP01 3 Beyond the Dipole Approxiamtion: Angular - Distribution Effects in the 1s Photoemission from Small Molecules* O.A. HEMMERS, *Univ. of Nevada, Las Vegas* H. WANG, *Univ. of Nevada, Las Vegas* D.W. LINDLE, *Univ. of Nevada, Las Vegas* P. FOCKE, *Univ. of Tennessee* I.A. SELLIN, *Univ. of Tennessee* J.A. SHEEHY, *Air Force Research Laboratory* J.D. MILLS, *Air Force Research Laboratory* P.W. LANGHOFF, *Indiana University* XAMS COLLABORATION, Over the past two decades, the dipole approximation has facilitated a basic understanding of the photoionization process in atoms and molecules. Our experiments on the 1s inner shells of small molecules at relatively low photon energies (< 1000 eV) show strong non-dipole effects. They are significant and measurable at energies close to threshold, in conflict with a common assumption that the dipole approximation is valid for photon energies below 1 keV. The effect is attributed on basis of concomitant theoretical analysis to the displacement of the 1s charge distributions from the molecular center of mass, providing a much larger effective charge distribution of molecular dimensions consequent of rotational averaging over which the phase of the incident radiation can vary significantly.

*This work was supported by DOE, NSF, DFG, Research Corporation, and The Petroleum Research Fund

NP01 4 Post Collision-Interaction Effects in H_2S* D.L. HANSEN, *Dept. of Chemistry, University of Nevada, Las Vegas* G.B. ARMEN, *Dept. of Physics, University of Tennessee, Knoxville* J.P. COTTER, *Dept. of Physics, University of Nevada, Reno* G.R. FISHER, *Lawrence Berkeley National Laboratory* K.T. LEUNG, *Dept. of Chemistry, University of Waterloo, Canada* R. MARTIN, *Dept. of Chemistry, University of Nevada, Las Vegas* P. NEILL, *Dept. of Physics, University of Nevada, Reno* W. NG, *Lawrence Berkeley National Laboratory* R.C.C. NP01 5 Resonant Auger studies in Kr 3d3/2,5/2-1np states using angle-resolved electron imaging spectroscopy AHMAD FARHAT, *Western Michigan University* ANT WILLS, *Western Michigan University* BURKHARD LANGER, *Techniche Universitat Berlin* NORA BERRAH, *Western Michigan University* An extensive and detailed mapping of the resonant Auger decay of all the photoexcited 3d3/2,5/2-1np states in Kr has been performed using angle resolved two-dimensional photoelectron spectroscopy at the Advanced Light Source. This has allowed us to obtain angular distributions, spectator and shake probabilities for the Kr 3d-1np –> 4s-14p-1(1P)mp + e- (n = 5-9, m = 5-11) resonance Auger decays. The results show that the spectator-core coupling is strong at lower n (n = 5,6) but it lessens for higher n, with a shake-up of m = n+1 preferred. The observed trend is in good agreement with the previous experimental and theoretical spectator and shake probabilities for these transitions and also with the analogous decay to the 4s24p4mp states (Aksela et al. [1]). However, no prior angular distribution measurements for the Kr 3d-1np –> 4s-14p-1(1P)mp + e- (n = 5-9, m = 5-11) resonant Auger decay has been reported. These are found to also show similar behavior to the decay to the 4s24p4mp states. [1] H. Aksela, M. Kivilompolo, E. Nmmiste, and S. Aksela Phys. Rev. Lett. 25, 4970 (1997).

NP01 6 First spin-resolved gas-phase studies at the ALS* G. SNELL, *Lawrence Berkeley National Laboratory, Berkeley, CA 94720* B. LANGER, *Fritz-Haber-Institut der MPG, 14195 Berlin, Germany* J. VIEFHAUS, *Fritz-Haber-Institut der MPG, 14195 Berlin, Germany* E. KUKK, *Lawrence Berkeley National Laboratory, Berkeley, CA 94720* J. BOZEK, *Lawrence Berkeley National Laboratory, Berkeley, CA 94720* N. BERRAH, *Western Michigan University, Dept. of Physics, Kalamazoo, MI 49008* One way to accomplish a so-called complete photoionization or Auger electron emission experiment is to use circularly polarized radiation to determine the spin polarization vector of the outgoing electrons. The new EPU beamline of the ALS will deliver highly circularly polarized light in the important photon energy range of 100-1000 eV. To perform spin-resolved gas-phase experiments, we have developed a new apparatus consisting of a time-of-flight electron energy analyzer combined with a retarding field Mott detector. In a first investigation, we have measured the spin polarization of the Xe $5p^{-1}P_{1/2,3/2}$ and $4d^{-1}D_{3/2,5/2}$ photolines parallel to the photon beam. The measurements were performed with linearly polarized light. Our main objective for the near future is to study the spin polarization of photo- and Auger electrons of atomic and molecular gas-phase targets after photoionization with circularly polarized radiation.

NP01 7 Rotationally resolved spectra of the $3p\,^1\Sigma_g^+$ gerade Rydberg state of acetylene. S. BENZAID, F. DI TEODORO, E. F. McCORMACK, *Bryn Mawr College* Although the gerade Rydberg states of acetylene (C_2H_2) are of interest to many, information on these states has remained limited due to their predissociative character and the prohibitive selection rules for their excitation from the ground state. By using a two-color resonantly-enhanced, multiphoton ionization (REMPI) technique however, the gerade Rydberg states may be probed in a state-selective manner that allows the observation of their rovibronic structure. As part of an ongoing study of the gerade Rydberg states in acetylene, the rotational structure of the $^1\Sigma_g^+$ component of the $3p$ state, the lowest member of the gerade Rydberg complex, has been investigated. Analysis of the rotationally resolved spectra corresponding to transitions from the $V_0^3K_0^1$ vibrational level of the intermediate $\tilde{A}^1A_u$ electronic state to the 0^0 vibrational level of the $3p\,^1\Sigma_g^+$ Rydberg state yields rotational constants and information on the geometry of the $\tilde{X}^2\Pi_u$ ground electronic state of the $C_2H_2^+$ ion. Several unexpected features are observed in the spectra and the possible implications of these observations on the assumed linear geometry of the state will be discussed.

NP01 8 Multi-channel B-spline based K-matrix approach T. K. FANG, *Inst. Atomic and Molecular Sciences, Academia Sinica, Taiwan* T. N. CHANG, *Dept. Phys. and Astro., Univ. Southern Calif., LA, CA* A multi-channel B-spline based K-matrix approach for the multiple continua is presented as an extension of the B-spline based configuration interaction approach (BSCI) for a single ionization channel. [1] Applications to photoionization of He to multiple continua from the ground and bound excited states will be presented. Results of our calculation agree well with other existing theoretical and experimental results. This work is supported by the NSF. [1] T. N. Chang, in "Many-body Theory of Atomic Structure and Photoionization," edited by T. N. Chang (World Scientific, Singapore, 1993), p. 213

NP01 9 Photoabsorption of Mg above the 3p threshold H. S. FUNG, H. H. WU, T. S. YIH, *Dept. Physics, National Central Univ., Taiwan* T. K. FANG, *Inst. Atomic and Molecular Sciences, Academia Sinica, Taiwan* T. N. CHANG, *Dept. Phys. and Astro., Univ. Southern California, LA, CA* We present the results of a joint experimental and theoretical study of the autoionization structures of Mg atom at energies above the $3p^2P$ threshold. The absolute photoabsorption cross sections are determined by measuring the light attenuation through a heatpipe using the synchrotron radiation. [1] The observed spectra are compared with the theoretical spectra using a B-spline based multi-channel K-matrix approach. In particular, the "hidden" $3d4p\,^1P$ resonance missing from the observed Mg ground state photoabsorption spectrum is analyzed in detail. Theoretical spectra from bound excited states will also be presented. This work is supported in part by the NSC in Taiwan and the NSF in the US. [1] C. C. Chu, H. S. Fung, H. H. Wu, and T. S. Yih, J. Phys. B31, 3843 (1998).

NP01 10 Observation of the $3snd\,^1D$ to the $3png\,^1F$ Autoionization Resonances in Mg* A.H. KUNG, W.J. CHEN, C.K. NI, T.K. FANG, *IAMS, Acad. Sinica, Taiwan* T.S. YIH, *NCU, Taiwan* T.N. CHANG, *USC* Intense ultranarrow resonances have been observed in the photoionization of Mg from the excited $3snd\,^1D$ states to the doubly-excited $3png\,^1F$ autoionization states using stepwise laser excitation and time-of-flight mass spectrometry detection. These resonances are the result of the $3pg$ configuration series interacting with the $3pd$ configuration series and mixing substantially with the $3sf\,^1F$ continuum, acquiring a large strength for the normally weak $3snd - 3png$ transition. Comparison of the measured line positions and transition widths with results derived from the B-spline-based configuration interaction calculations are presented[1].

*Supported by NSC Taiwan, and NSF.

NP01 11 Photoionization of Multiply-Charged Positive Ions using an ECR Ion Source and Synchrotron Radiation. J.-M. BIZAU, J.M. ESTEVA, D. CUBAYNES, F. J. WUILLEUMIER, *LSAI, University Paris-Sud, Orsay* R. MARMORET, R. REMOND, C. COUILLAUD, A. COMPANT LA FONTAINE, C. BLANCARD, *CEA/DIF, BP12, 91680 Bruyères-le-Châtel* D. HITZ, P. LUDWIG, *CEA, CENG, Grenoble* Experimental data on the interaction of the electromagnetic radiation with ions are very scarce, because of the experimental difficulties to confine a plama of highly-charged ions in a small volume for a long enough period of time. A new experimental set-up has been built to study photoionization processes in multiply-charged ions using synchrotron radiation emitted from the SU6 undulator of the Super-ACO storage ring in Orsay. Ions are produced in a permanent-magnet 10 Ghz-ECR ion source, then a Wien filter allow us to select the ionic species to be studied. After deflection by an electrostatic quadrupole, the ion beam is merged with the monochromatic photon beam. The ions which are produced in the interaction of the photon beam with the incident ion beam are analyzed by ionic spectrometry. The characteristics of the experiment will be described and preliminary results will be presented at the conference.

NP01 12 A variable matter wave beam splitter KLAAS BERGMANN, HEIKO THEUER, RAZMIK UNANYAN, CHRISTA HABSCHEID, KATRIN KLEIN, *Fachbereich Physik der Universität, D-67653 Kaiserslautern, Germany* We demonstrate a robust variable beam splitter for Ne atoms based on a modified scheme of stimulated Raman adiabatic passage (STIRAP) in the form of a

tripod linkage. A pump laser couples the initially populated level (the metastable J = 0 state) to an intermediate one. Two Stokes radiation fields (same frequency but different circular polarizations) couple the intermediate state to the m = + 1 and m = - 1 states of the J = 2 level. The interaction with both Stokes fields begins earlier than the interaction with the pump field. When the time dependence of the Stokes interactions is idential, the splitting ratio is 50:50. The splitting ratio can be controlled by the time delay between the interaction of one Stokes field relative to the other. The features of this variable beam splitter, and its robustness, are determined by the controlled nonadiabatic couplings between the two dark states of the systems.

NP01 13 Single Ionization of He and H^- by Compton Scattering. S. ITZA-ORTIZ, J.H. McGUIRE, *Tulane University* J. WANG, *University of Massachusetts-Dartmouth.** The differential cross section per unit energy tranfer for single ionization of He and H^- is calculated and compared to the corresponding Compton cross section by one and two free electrons. The incoming photon energy varies from 6 to 40 KeV. For the initial state we use fully correlated configuration-interaction type wave functions expanded in terms of Sturmian functions, using as many as 35 terms. For the final state we use uncorrelated wave functions. Our results show that the He cross section is comparable to the cross section by two free electrons, while the H^- cross section is between the cross section for one and two free electrons. Our results are in a range of energy transfer larger than the atomic threshold, and extending a little beyond the binary encounter limit. Near threshold only a few partial waves contribute in contrast to higher energy transfer where many partial waves contribute, unlike photoannhilation.

NP01 14 Quantitative Measurements of Dynamic Partitioning of Angular Momentum of Valence Electrons During the Autoionizion of Ar** D.H. JAECKS, O. YENEN, K.W. McLAUGHLIN, *University of Nebraska-Lincoln*† We have produced the autoionizing states Rydberg states $\{3p^4[^1S]4s\}^2S - np$ of Ar** using linearly polarized light of high resolution at the Advanced Light Source Synchrotron. For this state the angular momentum and any resulting magnetic substate distributions (alignment) reside entirely in the outer np Rydberg electron, with the ^2S core being spherically symmetric. In this case the np electron is in an $m = 0$ state since it is formed with linearly polarized light. By measuring the polarized fluorescence of the $Ar^+\{3p^4[^3P]4p\}^2D^O(J = 5/2)$ state that is formed in the autoionization process, we have determined the alignment of $A(J)$ of the $J = 5/2$ state. Using standard angular momentum recoupling procedures[1], we have determined the alignments $A(L)$ of the $L = 1$ core and $A(\not{\ell})$ of the $4p$ electron. Our results indicate a significant redistribution of the angular momentum that originally resided in only the np electron to angular momentum of the $3p$ and $4p$ electrons, as well as the free electron.

NP01 15 Analysis of $2l2l'n''l''$ resonances in the photoionization of $1s^22p$ excited Lithium* HSIAO-LING ZHOU, STEVEN T. MANSON, *Georgia State University, Atlanta* LAN VO KY, PAUL FAUCHER, *Observatoire de Nice* Total and partial cross sections for photoionization of the $1s^22p\ ^2P^o$ lithium excited state have been calculated using the R-matrix code. We decomposed the total and partial cross section into its component $SL\pi$ final states to determine the resonance positions. In addition we used the eigenphase derivative technique (QB method) to obtain 19 series of $2l2l'n''l''$ resonance positions and effective quantum numbers, $n^* = n - \mu_n$ for n as high as 22. We found a number of series perturbations among the resonances. The strong resonances and resonance series without perturbations converge to a constant quantum defect quickly; these include $2s2p(^1P)np\ ^2S^e$, $2p^2(^1S)ns\ ^2S^e$, $2s2p(^1P)np\ ^2P^e$, $2s2p(^1P)np\ ^2D^e$. The strong resonances are found to perturb the weak ones. For example, the weak $2s^2(^1S)7d\ ^2D^e$ resonance is perturbed by the stronger $2s2p(^3P)4p\ ^2D^e$ so that the quantum defect for the $2s^2(^1S)7d\ ^2D^e$ does not follow the rest of series. Further this weak resonance has ''borrowed'' a bit of the oscillator strength of the strong one, making it more stronger than the other members of the series. Similarly $2s^2(^1S)10s\ ^2S^e$ is perturbated by the strong ''neighbor'' $2s2p(^3P)4p\ ^2S^e$. Owing to these strong perturbations, the quantum defect for weaker series converge only for very high n.

NP01 16 Inner-shell Photoabsorption of X-Rays by Atomic Carbon and Nitrogen KATE P KIRBY, *Harvard Smithsonian CfA* BRENDAN M McLAUGHLIN, *The Queens University of Belfast* Cross sections for inner-shell photoabsorption by atomic carbon and nitrogen, are being calculated with multi-configuration target wave functions using the R-matrix approach in the soft x-ray energy range. Various direct and Auger auto-ionizing processes contributing to the cross sections are analyzed and discussed. In the vicinity of the carbon and nitrogen K-edges the theoretical cross section results show a wealth of structure. Analogous calculations for atomic oxygen showed good agreement with recent synchrotron measurements[1]. For carbon and nitrogen, little experimental data is available, but accuracies similar to those for oxygen are expected and comparisons are made whenever possible.

NP01 17 Comparison of the Photoelectron Angular Distributions of C^-, Si^-, and Ge^- at Visible Photon Wavelengths A. M. COVINGTON, D. L. CARPENTER, J. S. THOMPSON, W. W. WILLIAMS, *University of Nevada, Reno** The photoelectron angular distributions of C^-, Si^-, and Ge^- have been measured at discrete visible photon wavelengths. The measurements were performed at the University of Nevada, Reno. Negative ion beams of carbon, silicon, and germanium were extracted from a cesium-sputter negative ion source, and mass analyzed using a 90° bending magnet. The negative ion beam of interest was then crossed at 90° with a photon beam from a cw 25-Watt Ar^+ laser. The photon beam was linearly polarized ($\geq 10^5$:1) and the polarization vector was rotated with respect to the photoelectron collection direction with a double Fresnel rhomb. The resulting photoelectrons were energy analyzed with a 160° spherical-sector spectrometer. Photoelectron yields, $Y(\theta)$, were collected at discrete angles and then fit to the function $Y(\theta) \propto \frac{\sigma}{4\pi}(1 + \beta P_2(\cos\theta))$ to determine the asymmetry parameter, β. The spectral dependence of the photoelectron asymmetry parameters of C^-, Si^-, and Ge^- are compared to each other and fit to a straightforward model of the asymmetry parameter for photodetachment of p-electrons[1].

NP01 18 Measurement of the Electron Affinities of Indium and Thallium J. S. THOMPSON, D. L. CARPENTER, A. M. COVINGTON, W. W. WILLIAMS, *University of Nevada, Reno* T. J. KVALE, *University of Toledo* D. G. SEELY, *Albion College** The electron affinities of indium and thallium were measured in separate experiments using the laser-photodetachment electron spectroscopy technique. The measurements were performed at the University of Nevada, Reno. Negative ion beams of both indium and thallium were extracted from a cesium-sputter negative ion source, and mass analyzed using a 90° bending magnet. The negative ion beam of interest was then crossed at 90° with a photon beam from a cw 25-Watt Ar^+ laser. The resulting photoelectrons were energy analyzed with a 160° spherical-sector spectrometer. The electron affinity of $In(^2P_{1/2})$ was determined[1] to be 0.404± 0.009 eV and the electron affinity of thallium was determined to be 0.377 ± 0.013 eV. The fine-structure splittings in the ground states of the negative ions were also determined. The experimental measurements will be compared to several recent theoretical predictions.

NP01 19 Identification of Two-Electron Resonances in He^- ($1s2s2p\ ^4P^o$) Photodetachment* CHIEN-NAN LIU, ANTHONY F. STARACE, *The University of Nebraska – Lincoln* We present eigenchannel R-matrix results for He^- photodetachment partial cross sections in the energy region above the n=4 thresholds, stimulated by recent measurements of the He($1s3p\ ^3P$) partial cross section in which a large number of unidentified resonances are found[1]. Since the energy region considered is much lower than the *1s* excitation energy, we treat He^- as a quasi two-electron system. Owing to the three final state channels which contribute to the He($1s3p\ ^3P$) partial cross section, it is difficult for experiment to identify the resonances. Our calculations give good overall agreement with the experimental measurements. We also identify all resonance structures and demonstrate their effects on the partial cross sections, even though many of them are not well resolved in the measurements. Propensity rules for populating certain doubly-excited states are discussed, as well as the induced polarization model proposed in the experimental paper[1]. *Work supported in part by the U.S. Department of Energy, Division of Chemical Sciences, Office of Science under Grant No. DE-FG03-96ER14646.

DAMOP: COOLING AND TRAPPING

NP01 20 Progress Toward a Sympathetically-cooled Positron Plasma* B.J. JELENKOVIC, J.J. BOLLINGER, A.S. NEWBURY, T.B. MITCHELL, D.J. WINELAND, *NIST, Boulder, CO 80303* We plan to use laser-cooled $^9Be^+$ ions to trap and sympathetically cool positrons in a cylindrical Penning trap. High energy positorns from a Na^{22} source pass through a $^9Be^+$ plasma before striking a Cu(111) single crystal moderator. As the positrons pass back through the plasma, axial momentum can be converted to perpendicular momentum and the positrons can be temporarily trapped. The positrons can then cool by cyclotron radiation and sympathetic cooling with the cold $^9Be^+$ and become permanently trapped. Estimates of the trapping efficiency will be discussed. We have been able to trap ~ 1 mm long, ~ 10 $^{10}cm^{-3}$ $^9Be^+$ which we think will be useful for traping positrons. In this experiment we have also observed non-sheroidal plasma shapes due to deviations from a quadratic trapping potential. These deviations become pronounced when a plasma is axialy thin (radial size is much larger then axial thickness). The measured plasma shapes will be compared with a global thermal equlibrium computation.[1]

NP01 21 Mode Studies of Laser-Cooled Be^+ Ion Plasmas in a Penning Trap.* T.B. MITCHELL, J.J. BOLLINGER, X.-P. HUANG, W.M. ITANO, *NIST, Boulder, CO 80303* We trap up to 10^6Be^+ ions in a Penning trap and utilize laser cooling to reduce the ion temperature to less than 5 mK. In this regime, the ions are an excellent experimental realization of the one-component plasma (OCP). The plasma shape is spheroidal and analytic solutions exist for all of the modes.[1] We non-destructively measure the plasma shape from the ion fluorescence induced by the cooling laser. Plasma modes are excited with sinusoidally time-varying potentials applied to the trap electrodes, and imaged by changes in the ion resonance fluorescence produced by Doppler shifts from the coherent velocities of the mode. A comparison with theory of measurements of mode eigenfunctions and frequencies shows good agreement. The damping of the modes can be measured by sweeping the frequency of the perturbation through a mode frequency, while measuring the mode's resultant amplitude and phase. Preliminary measurments show damping rates consistent with the rates of viscous damping seen in simulations; the scaling of the damping with temperature and particle number will be presented.

NP01 22 Resonance Fluorescence of Two Closely Spaced Trapped Ions DANA BERKELAND, *Los Alamos National Laboratory* The distance between two trapped ions can be on the scale of a wavelength of the atomic transition. This opens a relatively new regime of quantum optics, in which the properties of the resonance fluorescence can be measurably modified. For example, super- and sub-radiance[1] has been demonstrated in two barium ions confined in a spherical Paul trap[2]. With two strontium ions tightly confined in a linear Paul trap, this effect can be made more pronounced. Also, the dependence of the transition frequency on ion spacing[3] may be measured, and population transfer between two ions[4] may be demonstrated. In the process of setting up these experiments, other experiments may be done in a less tightly confining trap. I will describe progress in the developement of the laser system and ion trap construction for these experiments.

NP01 23 Velocity-Resonant Precession* M.J. BELLANCA, L. LIU, T. BERGEMAN, H. METCALF, *Physics Dept., SUNY, Stony Brook, NY 11794-3800* G. RAITHEL, *Physics Dept., Univ. Michigan, Ann Arbor, MI 48109* We have measured Velocity Selective Resonances (vsr)[1] that are narrower than the few-recoil widths expected from sub-Doppler laser cooling theory[2]. Consider a circularly polarized standing wave with $\vec{k}$-vectors along $\hat{z}$, and a B-field along $\hat{x}$. Atoms with $M_J = J$ at the standing wave node (no excitation), that travel a distance $\lambda/2$ in one Larmor precession time, arrive at the antinode with $M_J = -J$ where excitation by the strong light field is minimized by the small Clebsch-Gordan coefficent. This speed is $v = \omega_z/2k \equiv v_{vsr}$, exactly the condition for vsr. Just like dark states, atoms with $v = v_{vsr}$ experience a minimal excitation rate, so they undergo less momentum diffusion, and thus collect in a narrow range of velocities. Atoms with speeds $v \neq v_{vsr}$ scatter light preferentially from one beam or the other and thus experience a force pushing them toward v_{vsr}. Thus the Zeeman coherences among ground state sublevels produce quasi-dark states (related to ground state quantum beats). This interpretation is supported by calculations of the lifetimes of the quasi-dark states and by QMCWF calculations. These permit analysis of the cooling dynamics as well as of the steady state, and also identification of magnetic dipole autocorrelation functions.

NP01 24 Precise Measurements of the Bichromatic Force* M.R. WILLIAMS, M.T CASHEN, F. CHI, H. METCALF, *SUNY Stony Brook, NY 11794-3800* The limit on the magnitude of radiative forces of $\hbar k\gamma/2$ imposed by the spontaneous decay rate γ of the excited state can be overcome by coherent control of the momentum exchange between atoms and the light field. This can be implemented with light beams containing two frequencies in the form of rectification of the dipole force, but its velocity range is limited to $\sim \gamma/k$. Recently there has been a demonstration of beam slowing by the very strong bichromatic force whose velocity range is limited only by laser power[1]. We have made precise measurements of this bichromatic force by deflecting a thermal beam of Rb atoms. We used a standing wave of circularly polarized light whose components had carefully chosen relative phases, amplitudes, and frequency differences. Our results show its extremely large magnitude and velocity range, and also show that its velocity dependence near the edge of the range is suitable for atomic beam slowing and laser cooling. Our measurements have corroborated various models and calculations of this bichromatic force in great detail.

NP01 25 Dipole-force atom traps using Laguerre-Gaussian modes of diode lasers* SHARON A. KENNEDY, J. TOM FARRAR, ERIC R. I. ABRAHAM, *University of Oklahoma* Bose-Einstein condensation (BEC) in weekly-interacting gasses may lead to important advances in atomic physics: better atom interferometers, more accurate and precise atomic clocks, and highly improved probes of atomic interactions. There is also considerable interest in BEC as a laboratory to study phenomena that might give new insights into strongly interacting systems such as superfluids and superconductors. A major step towards the realization of this goal is the creation and study of vortices and persistent currents, effects not yet observed in atomic gas condensates. We will present progress towards developing a new set of optical atom traps by transforming the Gaussian output mode of a diode laser into various Laguerre-Gaussian (LG) propagation modes using diffraction gratings. These modes exhibit the distinguishing characteristic of a note in the center of the intensity profile cross-section. Higher order LG modes have multiple radial nodes, allowing a wide variety of trap potential geometries. This can open the door to create effectively 1D and 2D confining potentials as well as toroidal traps that will allow new studies of BEC including the creation and stabilization of vortices and persistent currents.

NP01 26 Atom Guiding by a Dark Hollow Laser Beam KWANIL LEE, *Department of Physics, Seoul National University, Seoul 151-742, Korea; Center for Nearfield Atom-Photon Technology, Seoul National University, Seoul 151-742, Korea* XINYE XU, *Center for Nearfield Atom-Photon Technology, Seoul National University, Seoul 151-742, Korea; Quantun Optics Laboratory, Shanghai Institute of Optics and Fine Mechanics, Sanghai 201800, China* SEUNG HYUP YOO, *Center for Nearfield Atom-Photon Technology, Seoul National University, Seoul 151-742, Korea* YUZHU WANG, *Quantun Optics Laboratory, Shanghai Institute of Optics and Fine Mechanics, Sanghai 201800, China* WONHO JHE, *Department of Physics, Seoul National University, Seoul 151-742, Korea; Center for Nearfield Atom-Photon Technology, Seoul National University, Seoul 151-742, Korea* A dark hollow laser beam(DHB) is generated by properly collimating the output beam of the LP_{01} mode guided in the hollow-core optical fiber. The rubidium atoms are magneto-optically cooled and trapped, and then loaded into a blue-detuned DHB which propagates upwards and overlaps with atomic molasses. A near-resonant weak repumping beam is also added upwards. If the transverse kinetic energy of an atom is smaller than the optical potential of the blue-detuned DHB, the atom is reflected and guided along the DHB. We have observed the dependence of the flux of guided atoms on the detuning and intensity of DHB at a position 12 cm below the MOT. The cold guided atoms in the DHB will be directly coupled into the HOF without using a lens to enhance the phase space density of cold atoms inside the hollow-core fiber.

NP01 27 Novel Atomic Funneling into a Hollow Optical Fiber JONG-AN KIM, *Department of Physics, Seoul National University, Seoul 151-742, Korea; Center for Nearfield Atom-Photon Technology, Seoul National University, Seoul 151-742, Korea* KIHWAN KIM, *Department of Physics, Seoul National University, Seoul 151-742, Korea* SEUNG HYUP YOO, *Center for Nearfield Atom-Photon Technology, Seoul National University, Seoul 151-742, Korea* CHANGYEON WON, *Department of Physics, Seoul National University, Seoul 151-742, Korea* UNYOB SHIM, *Center for Nearfield Atom-Photon Technology, Seoul National University, Seoul 151-742, Korea* WONHO JHE, *Department of Physics, Seoul National University, Seoul 151-742, Korea; Center for Nearfield Atom-Photon Technology, Seoul National University, Seoul 151-742, Korea* We have produced a continuous cold atomic beam from the magneto-optical trap in the simple pyramidal hollow mirror system and coupled it into a hollow-core optical fiber. To make the coupling efficiency higher, we use a novel atomic funnel with the dark hollow beam directly produced by the hollow-core optical fiber. We combine two LP_{11} modes having node lines and polarization orthogonal to each other, so that the resulting mode has no nodes and can be used for efficient funneling atoms into the hollow optical fiber. The guided atoms will be used for atom lithography with a submicron-sized hollow-core optical fiber.

NP01 28 Magneto-Optical Trap for On-line Fr Spectroscopy J.S. GROSSMAN, R.P. FLILLER III , C. FRIEGANG, M. IFFERTE, L.A. OROZCO, M.R. PEARSON, B. PEKER, J.E. SIMSARIAN, G.D. SPROUSE, W.Z. ZHAO, *SUNY, Stony Brook NY* We have constructed a second generation magneto-optical trap for on-line capture of radioactive francium at the Stony Brook Superconducting LINAC. We produce francium isotopes via the ^{16,18}O (^{197}Au,xn) or ^{19}F(^{198}Pt,xn) reactions, in the target room of the accelerator. We then extract and transport the activity using electrostatic optics to a different room where we neutralize and capture the atoms in a Magneto-Optical trap (MOT). Tests with Rb show greater than 90 percent transport efficiency, and we have delivered over 3×10^6 Fr/sec to a Faraday cup in front of the trap. We are currently characterizing the MOT with a beam of stable Rb ions that follow the same path as that of the Fr. This new trap will function as the accumulating trap to fill a purely optical trap for further studies with Fr. The new possibility of working next to the Fr atoms, in contrast with our previous situation where we worked remotely, will permit direct optimization of the traps without remote control of the experiments. This work is supported by the NSF and REU supplements from the NSF.

NP01 29 Compact Cold Atom Clock for Space Applications W. F. BUELL, *The Aerospace Corporation* Highly stable atomic frequency standards are of increasing importance for a variety of space applications, ranging from communication to navigation and time transfer to tests of fundamental science. We present a new design for a compact Cs beam atomic clock suitable for space applications and featuring a cold atomic beam source based on a single beam, conical mirror MOT with a hole at the apex to produce a low velocity high flux atomic beam. This cold atomic beam is then used in a laser-pumped Ramsey clock, with the clock signal derived from either a microwave C-field or alternatively by Raman resonance between the Ramsey fields. In order to reduce light shifts from the MOT light, the atomic beam is deflected and transversely cooled upon exiting the MOT's conical reflector. Initial numerical estimates indicate that a short term Allan varaince of $\sigma_y(\tau) \approx 3 \times 10^{-14}\tau^{-1/2}$ should be achievable with this design. We will present our experimental progress towards a working frequency standard.

NP01 30 Progress Towards Creating a Quantum Degenerate Fermionic System with Radioactive Rb Isotopes SCOTT CRANE, *Los Alamos National Laboratory and Utah State University* RALF GUCKERT, WAYNE TAYLOR, DAVID VIEIRA, XINXIN ZHAO, *Los Alamos National Laboratory* ERIC BURT, *U. S. Naval Observatory* FRANK ABEELEN, BOUDEWIJN VERHAAR, *Eindhoven University of Technology* Progress in trapping large numbers of radioactive ^{82}Rb atoms ($\tau_{1/2}$[1]) has opened up the possibility of studying quantum degenerate systems with fermionic Rb isotopes. Theoretical calculations indicate that the scattering length of ^{84}Rb/^{87}Rb and ^{86}Rb/^{87}Rb are large and positive, a desirable condition to achieve Fermi degeneracy through sympathetic cooling of ^{84,86}Rb ($\tau_{1/2}$ days, respectively) with evaporative cooled ^{87}Rb atoms. Recently, we have demonstrated the simultaneous trapping of ^{85}Rb and ^{87}Rb atoms in a TOP trap constructed for a beta-asymmetry measurement of polarized ^{82}Rb. The latest progress and plans in trapping a mixture of ^{84,86}Rb/^{87}Rb for quantum degeneracy studies will be reported. [1] R. Guckert, et al. PRA 58 R1637 (1998).

NP01 31 GLACE: A Technology Demonstration Experiment for Laser Cooled Atomic Clocks in Space R. J. THOMPSON, J. KOHEL, W.M. KLIPSTEIN, D. J. SEIDEL, L. MALEKI, *Jet Propulsion Laboratory, California Institute of Technology, Pasadena, CA 91109* K. GIBBLE, *Physics Department, Yale University, New Haven, Connecticut 06511* We have been developing a laser-cooling apparatus for flight on the International Space Station (ISS), with the intention of demonstrating linewidths on the cesium clock transition narrower than can be realized on the ground. GLACE (the Glovebox Laser-cooled Atomic Clock Experiment) is scheduled for launch on Utilization Flight 3 (UF3) in 2002, and will be mounted in the ISS Glovebox platform for an anticipated 2–3 week run. Core technologies for this and other LCAP missions are being developed at JPL. Significant technical challenges in developing a space qualifiable laser cooling apparatus include reducing the volume, mass, and power requirements, while increasing the ruggedness and reliability in order to both withstand typical launch conditions and achieve several months of unattended operation. This work was performed at the Jet Propulsion Laboratory under a contract with the National Aeronautics and Space Administration.

NP01 32 Generation of a cold atom beam from a pyramidal magneto-optical trap J.L. BLISS, K.G. LIBBRECHT, *California Institute of Technology, Pasadena, California 91125* J. KOHEL, R.J. THOMPSON, D.J. SEIDEL, W.M. KLIPSTEIN, L. MALEKI, *Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91109* We have built an atomic beam source utilizing a simple and robust design based on the pyramidal trap geometry of Kim *et al.* (Opt. Lett. **22**, 117 (1997)). Our design allows use of a single large diameter ($\leq$ 20 cm) laser beam to obtain large capture rates of atoms from a background vapor. A small (1 mm diameter) hole in the retro-optic at the apex of the pyramid provides an extraction column for the atoms. We have operated the apparatus both as a magneto-optical trap (using an auxiliary plug laser beam), and as a cold atomic beam source. The characterization of this large pyramidal beam source will be reported, including an investigation of scaling to very large (10–20cm) high power (1 W) laser beams which should allow significant improvements in atomic beam flux.

NP01 33 Improved Loading and Lifetimes in a Far-Off Resonance Trap KRISTAN L. CORWIN, SIMON J. M. KUPPENS, KURT W. MILLER, CARL E. WIEMAN, *U. of Colorado and NIST, JILA, CB 440, Boulder CO 80309-0440* We have confined large samples of Rb in deep far-off resonance traps (FORT's). Enhanced loading is achieved by using a magneto-optical trap (MOT) to cool atoms as they enter the FORT. We have investigated the dependencies of this cooling process on laser power and frequency, and characterized the trap temperatures and densities using both fluorescence and absorption imaging. In addition, intensity stabilization of the trap laser has been used to substantially increase the trap lifetime in certain regimes. These large FORT samples are transferred into a circularly-polarized FORT, described elsewhere at this meeting.

NP01 34 Magnetostatic control of atoms near surfaces I.G. HUGHES, P.A. BARTON, M. G. BOSHIER, P. ROSENBUSCH, C. V. SABA, B. E. SAUER, E. A. HINDS, *SCOAP, Univ. of Sussex, Falmer, Brighton BN1 9QH UK* We have demonstrated that a suitably magnetized surface can be used to retroreflect cold atoms. The evolution of an 18 μK cloud of ^{85}Rb atoms bouncing freely on a horizontal concave atom mirror was imaged directly up to the 14th bounce. Initially compact, the cloud is alternately col-

limated (odd bounces) and brought back to a focus (even bounces) when dropped from a height R/4 (R is the radius of curvature). An external uniform magnetic field added to the sinusoidal mirror field causes a corrugated potential from which the atoms bounce with increased angular spread. Varying the external field allowed us to control the shape of the reflected cloud. Magnetic surfaces can support the atoms against gravity. Additional electrostatic forces might then be used to manipulate the atoms in a horizontal plane.

DAMOP: CAVITY QED

NP01 35 Experiments with single ytterbium ions NAN YU, LUTE MALEKI, *JPL, California Institute of Technology, Pasadena, CA* Trapped ions are now widely used in generating frequency standards, studying fundamental physics, and implementing quantum computation. In this proceeding, we report our initial experimental results with single trapped Yb^+ ions. We have observed resolved micromotion-sideband spectrum in an allowed transition and demonstrated that it can be conveniently used in micromotion reduction. In addition, we have made lifetime measurements in the both $4f^{14}5d$ metastable states. Experimental design and progress toward cavity QED using the trapped ions will also be discussed.

NP01 36 Two-atom dark states in electromagnetic cavities G. J. YANG,*O. ZOBAY, P. MEYSTRE, *Optical Sciences Center, University of Arizona, Tucson, AZ 85721* We study the center-of-mass motion of two two-level atoms coupled to a single mode of an electromagnetic resonator. For the basic case of one atom being initially excited and the cavity mode in the vacuum state the atomic time evolution is found to be dominated by the appearance of quasi-dark states. These states, in which the initial excitation is stored in the internal atomic degrees of freedom and which possess a very small spread in momentum, are almost immune against photon loss from the cavity. We present an analysis of these states within and beyond the Raman-Nath approximation of atom optics.

*Permanent address: Department of Physics, Beijing Normal University, Beijing 100875, China.

NP01 37 Radiative Properties of Confined Fermi Gases BEREKET BERHANE, *Georgia Institute of Technology* T.A.B. KENNEDY, *Georgia Institute of Technology* We study the radiative behavior of a system of confined degenerate fermionic atoms. Using density matrix methods, we investigate the influence of quantum statistics on radiative lifetimes and the anisotropy of spontaneous emission profiles[1], including re-absorption of radiation within the trap.

NP01 38 Linewidth of a single-atom laser JAMES CLEMENS, *Miami University* PERRY RICE, *Miami University* SUSAN BURKE, *Miami University* We investigate the linewidth of a single-atom laser. The system of interest is a single four-level atom, essentially stationary in an optical cavity. In previous work on this system[1],[2].it has been shown that as β is increased, the photon statistics of this system has three regimes. For small β (less than 0.1) we have super-thermal light for all pump rates. As β increases to around 0.2 we find a peak in the photon number variance vs. pump, but this peak is much smaller and wider than in many-atom lasers with smaller β values. Finally, increasing β above 0.3 results in the emission of amplitude squeezed light. We have calculated the output spectrum of our system in these different regimes. We find that the linewidth does not narrow with increase in pump strength in the low β regime. In the moderate β, semiclassical regime, there is a decrease in the linewidth with pump, along the lines of the usual Schawlow-Townes relation. In the high β regime, where the light is amplitude squeezed, we find that the linewidth decreases with pump, but is above the Schawlow-Townes limit.

DAMOP: SURFACE INTERACTIONS

NP01 39 Laser-Generated Surface Acoustic Pulses: Nonlinear Elastic Properties and Adhesion Studies* AL.A. KOLOMENSKII, X. ZHAO, H.A. SCHUESSLER, *Texas A&M University* Nanosecond surface acoustic wave (SAW) pulses excited by a focused laser beam in solid materials were investigated. The nonlinear transformation of these pulses is connected with the nonlinear elastic moduli of the material. The possibility to solve the inverse problem of the determination of the nonlinear moduli from the measurements of the observed waveforms is demonstrated. Another aspect of the surface interaction, namely extremely high surface accelerations produced by the SAW pulses is also being studied. The detachment of small particles residing on the surface due to the inertial force is examined. The nonlinear transformation of the excited SAW pulses results in an increase of the surface acceleration and contributes to the detachment process extending it to very small particle dimensions. It is shown that the adhesion of fine particles with dimensions as small as 50 nm can be investigated.

*Supported in part by NSF grant No. DMR-9870143 and Research Enhancement grant at Texas A&M University

NP01 40 Silicon Microlithography Using Metastable Argon Atoms* S.B. HILL, C.A. HAICH, G.K. WALTERS, F.B. DUNNING, *Rice University* J.J. McCLELLAND, R.J. CELOTTA, *NIST* D. TANENBAUM, *Pomona College* J. HAN, H.G. CRAIGHEAD, *Cornell University* We have investigated the use of an intense $Ar(^3P_{0,2})$ metastable beam to pattern Si(100) surfaces. The $Ar(^3P_{0,2})$ flux at the sample was $\sim 2\times 10^{11}$ atoms sec^{-1} cm^{-2}. Two different approaches to patterning were studied. In the first, a hydrogen-passivated Si(100) surface was exposed to the beam, in the presence of a small partial pressure of O_2, using a 2000 line/inch grid as a mask. The hydrogen-passivation layer is removed in those areas exposed to the beam, allowing formation of an oxide layer. Immersion in a KOH solution then selectively etches the hydrogen-passivated regions, producing an image of the grid on the Si surface. In the second approach, a siloxane self-assembled monolayer (SAM) was first grown on the Si surface and then exposed to the beam through the grid. Metastable atom impact damages the SAM permitting pattern transfer through subsequent

plasma and chemical etching. Because intense $Ar(^3P_{0,2})$ metastable beams can be manipulated and focused using optical fields, the present techniques could be used to produce structures on Si(100) surfaces without the need for physical masks and with the potential for massively parallel fabrication.

NP01 41 Investigation ino the ionic diffusion of Rb & Na ions in sulfonated polystyrene JAMES DORNICIK, *Department of Material Scince and Engineering at SUNY Stony Brook* JEFF ASSELTA, *Deptartment of Material Science and Engineering at SUNY Stony Brook* MIRIAM RAFAILOVICH, *Department of Material Science and Engineering at SUNY Stony Brook* JONATHAN SOKOLOV, *Department of Material Science and Engineering at SUNY Stony Brook* DENNIS PEIFFER, *Exxon Research and Engineering Company* YURI STRZHEMECHNY, *Department of Physics at Queens College* STEVE SCHWARZ, *Department of Physics at Queens College* In the study we have investigated the diffusion of Rb ions verses the diffusion of polymer chains in sulfonated PS (Psssa). The following bi-layer samples were investigated: 1)psssaRb / psssaNa, 2)psssa / psssaRb 3)psssa / psssaNa with a 0.45% approximately 1000A thick and unless noted have a sulfonation level of 3.4% temperature of 150C to 170C at times of 4hrs to 36hrs. The samples were examined by Secondary Ion Mass Spectrometry. This revealed that the segmental fluctuation of the polymer resulted in rapid diffusion of the Rb ions relative to the translational diffusion of the polymer chains. The purpose of this study is to obtain a comparison of the diffusion rates of sulfonated polystyrene, with and without ions, to the the rates of normal polystyrene. We compared the results to reptation models modified to account for ionic interactions. This work is supported by the NSF, (MRSEC DMR-9732230) and the DOE(SG02-93-ER45481)

NP01 42 Heavy Ion Irradiation of Solids: Projectile Charge and Target Dependence of Electron Emission between 0^o and 180^o* H. ROTHARD, *CIRIL,CEA-CNRS UMR11, Caen, France* S. HAGMANN, *Kansas State University* Motivated by the recent observation of narrow electron jets (''spikes'') emitted along the ion beam axis in forward and backward directions we measured for Fluorine ions of 1.5 AMeV the complete angular distribution of electron emission from 0 eV up to 4000 eV (beyond the maximum of the ''Binary Encounter'' electron peak) as a function of the projectile charge state (q = 5+, screened, and 9+, bare) and the target nuclear charge Z (two extreme cases: carbon, Z = 6, and Gold, Z = 79). In particular, the low energy part of the angular distribution was investigated in a high resolution run (0-50 eV). Results on the charge state, target material and angular dependence of low energy ''cascade'' electrons, Auger electrons, electrons from collective excitation (plasmons) will be presented. The evolution of the electron emission characteristics along the beam axis with the angular resolution of the spectrometer will be presented confirming the existence of the jet like electron spikes. The relevance of the experimental cross sections for electron emission for model calculations in radiobiology (linear energy transfer LET) and energy deposition and track formation in solids will be discussed.

*Supported by Div. of Chem. Sciences, Office of Basic Energy Sciences, Office of Energy Research, U.S. Dept of Energy.

NP01 43 A new experiment for studying ion-beam interactions with frozen-gas targets. J.L. SHINPAUGH, L.H. TOBUREN, C. CHRISTOU, E.L.B. JUSTINIANO, *East Carolina University* We have recently constructed a new experiment at East Carolina University to study the interactions of ion beams with thin films of frozen gases. The experimental arrangements were initially developed at Pacific Northwest National Laboratory, where electron emission from collisions of fast protons with carbon foils were measured.[1] The experimental apparatus consists of a cyrogenically cooled target housed in a magnetically shielded ultra-high vacuum chamber. Gases introduced into the chamber condense on a cold copper foil target. Electrons emitted from the frozen-gas target are energy analyzed by a time-of-flight spectrometer that can be rotated around the target. Absolute electron-emission yields, differential in energy and angle, can be measured down to electron energies of 0.1 eV. For these systems, the electron yields are determined not only by the primary collision interactions, but also by the transport of the electrons through the bulk and the interaction of the electrons with the surface. Preliminary measurements for 10-50 keV protons will be presented, and potential applications, including the detection of ions sputtered from surfaces, will be discussed.

NP01 44 Calculation of charge transfer between an atomic projectile and a metal surface STEFAN A. DEUTSCHER, *Laboratoire des Collisions Atomiques et Moléculaires, Bât. 351, Université de Paris-Sud, 91405 Orsay, France* LUDGER WIRTZ, JOACHIM BURGDÖRFER, *Institute of Theoretical Physics, Vienna University of Technology, Austria, University of Tennessee, Dept. of Physics, Knoxville, TN 37996, and Oak Ridge National Laboratory, USA* The formation of atomic resonances during the interaction of an atomic particle with a metal surface allows under certain conditions resonant charge transfer to occur between the two participants. Due to the finite velocity of the ion approaching and leaving the surface, the dynamic charge transfer process is determined by the non-adiabatic coupling between these resonances as well as with electronic states of the surface band structure. Based on accurate resonance data, we present in this work results of our calculations for the charge transfer in a model system consisting of a hydrogen atom and an aluminium surface. Work supported by US DOE, Office of Basic Energy Sciences, Division of Chemical Sciences, under contract No. DE-AC05-96OR22464 with Lockheed Martin Energy Research, Inc. and the Austrian Science Foundation.

NP01 45 Calculation of dynamic charge transfer between an atomic projectile and an ionic crystal surface (H on MgO(100)) STEFAN A. DEUTSCHER, ANDREI G. BORISOV, VICTOR SIDIS, *Laboratoire des Collisions Atomiques et Moléculaires, Bât. 351, Université de Paris-Sud, 91405 Orsay Cedex, France* Lately, the charge state evolution of projectiles in low energy ($E \leq 10$ keV) collisions with insulating surfaces of ionic crystals has been studied extensively. A high *negative ion* yield from neutral H, O, and F projectiles was observed experimentally on alkali-halide surfaces [C. Auth *et al.*, Phys. Rev. Lett. **75**, 2292 (1995); Phys. Rev. A **57**, 351 (1998)] and explained theoretically by charge transfer via binary encounters (BE) of the projectile with the lattice anions [A. G. Borisov, V. Sidis, Phys. Rev. B **56**, 10628 (1997)]. Collisions of such projectiles with a MgO(100) surface yield, similar to alkali-halide targets, also a large negative ion fraction [S. Ustaze *et al.*, Phys. Rev. Lett. **79**, 3526 (1997)]. The efficient negative ion production is of interest for the design of low-flux negative ion beam sources, and in space research for the construction of neutral particle detectors. Moreover, most chemical reactions on surfaces involve an electron transfer, so it is desirable to understand this process. In this paper, we present our

theoretical results for the negative ion production from H projectiles during slow ($E \leq 100$ eV) collisions with a MgO(100) surface using the BE model for the charge transfer. Work supported by the European Union under contract No. ERBFMBICT971983.

NP01 46 Broadening of hydrogenic levels near thin metallic films* U. THUMM, *Kansas State University* P. KUERPICK, *SAP, D-69190 Walldorf* U. WILLE, *Hahn–Meitner Institute, D-14091 Berlin* We evaluate the width of resonantly broadened hydrogenic levels in the vicinity of thin metallic films in first–order perturbation theory. We calculate the electronic states of the film as eigenstates of a Jennings-type (LDA) potential. In order to include hybridization effects, we represent the hydrogenic levels in a parabolic (Stark) basis. The widths show characteristic, sawtooth shaped, oscillations as the film thickness is varied between 0.5 and 3 nm. These oscillations are related to threshold effects in the onset of resonant capture into a particular hydrogenic level. We analyze the influence of these quantum size effects on measurable parameters, such as electron capture probabilities of slow incident hydrogenic ions.

*Supported by the Division of Chemical Sciences, Office of Basic Energy Sciences, Office of Energy Research, U.S. DoE

NP01 47 New Close Coupling Approach for Ion-Surface Interactions* B. BAHRIM, U. THUMM, *J.R.Macdonald Laboratory, Kansas State University* Within a two-center close-coupling expansion, we rewrite the time- dependent Schrödinger equation for an active electron interacting with a slowly moving projectile and a metal surface as a system of coupled equations and solve this system numerically. In contrast to other close-coupling approaches (e.g. Ref.[1]), we fully discretize the active electrons motion in the metal subspace along the surface normal by using a discrete sum of Weyl wave packets[2]. For the H/Al system, we provide level shifts, transition rates for atom-metal transitions, the time evolution of the atomic and metallic population amplitudes, and excitation rates for one-electron transitions in the substrate.

NP01 48 Patterning Surfaces with Highly Charged Ions J. D. GILLASPY, L. P. RATLIFF, R. MINNITI, *National Institute of Standards and Technology, Gaithersburg, MD 20899-8420* We present results which demonstrate masked ion beam lithography using highly charged ions. An electron beam ion trap was used to deliver a continuous ion beam current of approximately 10 pA of Xe44+ onto a silicon wafer coated with one of two materials: (1) a commercial lithographic resist (PMMA, 400 nm thick) and (2) an ultrathin self assembled monolayer ($<$ 2 nm thick). The resists were covered with stencil masks with rectangular openings ranging from approximately 1 micrometers to 12 micrometers in width. Subsequent to exposure, the resists were developed and then imaged using atomic force microscopy (AFM), scanning electron microscopy, and optical microscopy. The results of these studies show effective patterning with edge resolutions of 100 nm or better, apparently limited by the commercial masks rather than fundamentals of the ion exposure process itself. For PMMA exposed to low doses, it was possible to observe single ion impact sites (24 nm diameter). Results of ongoing work involving the direct modification (no chemical development) of HOPG surfaces with Xe23+ and Xe44+ will also be reported.

DAMOP: X-RAY AND UV SPECTROSCOPY

NP01 49 Ab Initio Single and Multiple Scattering EXAFS Debye-Waller factors: Applications to medium and large size molecules NICHOLAS DIMAKIS, GRANT BUNKER, *IIT** This paper describes recent results using our approach to calculating self-consistently single (SS) and multiple-scattering (MS) Debye-Waller factors (DWF) on medium and large size molecular structures. The calculation of MS DWF, together with the Feff7 program allows us to simulate *ab-initio* EXAFS spectra for a given temperature systems with no adjustable parameters. In our first report[1] we calculate *ab-initio* and semi-empirically SS and MS DWF for small molecules using Raman, infrared and EXAFS spectra. Lately, we calculate DWFs for Zn tetrahedral imidasol, an active site of a metaloprotein that contains thirty two atoms using the semiempirical MNDO Hamiltonian. Unfortunately the semi-empirical Hamiltonians, although much faster than the *ab-initio* Density Functional Theory (DFT), would not provide accurate results for *any* molecule tested. In this report we test various samples using EXAFS spectra. Our approach takes advantage of commercially available molecular orbital programs. We have written additional programs which, using normal mode calculations, calculate the MS paths, and transparently interface with Feff7 to produce the EXAFS spectra. Results are in very good agreement with experimental EXAFS data tested.

NP01 50 X rays emitted by implanted Ar atoms B. D'ÉTAT-BAN, *C.I.R.I.L., Caen* G. GIARDINO, J.-P. BRIAND, O. TÜSKE, N. BÉCHU, *Équipe de Recherche Ions-Surfaces, Université P&M Curie, 4 place Jussieu, 75252 Paris cedex 05* A. S. SCHLACHTER, *Advanced Light Source, Lawrence Berkeley National Laboratory, Berkeley, CA 94720* Argon atoms were implanted in various solid targets (metals, semiconductors and insulators) at depths of the order of 1000 Å and K ionized with photons of energy slightly higher than the Ar K shell binding energy at the Advanced Light Source of the Lawrence Berkeley National Laboratory. The subsequent fluorescence of the Ar atoms was observed with a very high resolution SiLi detector. These fluorescence spectra have been compared to those emitted following the excitation of Ar atoms in a gas cell. The Kα lines of implanted Ar have been found shifted down in energy by about 2 eV for most targets, with respect to those of gas phase Ar, while the relative intensity of the Kβ and Kα lines is similar in gas and solid targets. A possible explanation involving coupling of ion levels with the solid will be discussed.

NP01 51 Measurement of Pressure Broadening and Shift for Hg 254-nm line by N_2* J. P. JACOBS, *University of Montana* R. B. WARRINGTON, *University of Washington*† We have performed a measurement of the collisional broadening and shift of the 254-nm line of Hg by N_2 for pressures below 400 Torr. We

used the 500 mW output of a commercial MOPA single-mode laser at 1016 nm which is first doubled to 508 nm using a KNb O_3 crystal then doubled again using a BBO crystal, both in external enhancement cavities. This system produces over 100 μW at 254 nm, and can be easily tuned over tens of GHz. The transmission through two vapor cells (one containing natural mercury and one containing natural mercury plus 40 − 400 Torr of N_2) as well as the laser intensity were monitored simultaneously while the laser was scanned. The well-known isotope shifts and hyperfine structures of natural mercury were used to calibrate the frequency scale. Our preliminary results are $\Delta\nu_S = -(2.533 \pm 0.011)$ MHz/Torr for the shift and $\Delta\nu_B = (8.996 \pm 0.028)$ MHz/Torr for the broadening (statistical uncertainty only); these represent a substantial improvement over earlier work. The measurements are motivated by ongoing time-reversal symmetry measurements at the University of Washington.

NP01 52 Experimental benchmarks of the relative 2p-3d $^1P_1$, $^3D_1$ excitation cross sections in neon-like ions G. V. BROWN, P. BEIERSDORFER, D. A. LIEDAHL, K. REED, S. B. UTTER, *LLNL* The $n=3\rightarrow 2$ $^1P_1$ and $^3D_1$ resonance and intercombination lines are two of the strongest spectral features exhibited by neon-like ions making them prime diagnostic candidates. However, a study of theoretical predictions of the relative cross sections of these two transitions reveals a wide variation, rendering this diagnostic unreliable. For example, in the case of Fe XVII, the calculated ratio varies between 2.7 and 4.7. To provide benchmarks for calculations we have done a systematic study of the intercombination to resonance line ratio for ions along the neon-like isoelectronic sequence between Cr^{14+} and Kr^{26+}. Our measurements employed the Electron Beam Ion Trap facility under conditions where the only line formation processes are electron impact excitation followed by radiative cascades. The measurements, thus, provide a clean platform for evaluating the accuracy of theoretical atomic data. We have compared our measured ratios with those predicted by a distorted wave calculation. Our comparison shows a systematic difference between theory and experiment of approximately 30%. This discrepancy clearly demonstrates the limits of approximations which are present in many calculations.

NP01 53 All-optical triple-resonance excitation of singlet nf Rydberg states of molecular hydrogen* WALLACE L. GLAB, *Texas Tech University* We have efficiently excited singlet nf Rydberg states of molecular hydrogen using a triply-resonant process driven by vuv and visible tunable pulsed lasers. The first excitation step uses vuv light near 111 nm to excite specific rotational states of the B (v''=0) state. The vuv light is produced through a non-resonant four-wave mixing process in a phase-matched mixture of krypton and argon gas. A second laser operating near 460 nm then further excites the molecules to selected rotational and vibrational levels of several possible ns, nd intermediate states, including the G,K (v'=0 and 1) and several other 3dλ electronically excited states. A third, near-infrared tunable dye laser finally excites the molecules into high principle quantum number p and f states. Both ion production due to pulsed field ionization and photoionized dissociation products are monitored in the experiment. The Rydberg spectra show relative intensity effects due to both the choice of intermediate state and the excited state dynamics.

NP01 54 Nuclear Structures Predicted by the Checker Board Model THEODORE M. LACH, The Checker Board Model (CBM) explains many aspects of the nucleus. The CBM predicts that the de Broglie wavelength of the up quark in the proton equals the circumference of the proton, just like the Bohr model of the atom, only 100,000 times smaller. It is one of the few models that uses quarks to explain the strong force. It can explain a wide variety of structures: halo nuclei, linear alpha chains, and the more stable structures. It predicts that Fe 56 will be the most stable nuclei. It can predict the binding energy of a nucleus based upon the number of nearest neighbor sites (1,2,3,or 4). The CBM model therefore supports the 1979 Tamagaki's two dimensional ordered states model. Since the two protons (and neutrons) in the alpha particle have opposite spin orientations, the magnetic flux couples between these two, making the paired structure more stable. One addition item in support of this model: the mass difference between the two excited states of the pi meson (Phi(1020) and W(782)) is 237.47 +-.13 MeV, making this value almost the same, considering uncertainty, as the predicted mass of the up quark in the CBM model (237.31 MeV). These two excited pi meson states are significant since they both have all the same quantum numbers.

NP01 55 Checker Board Model THEODORE M. LACH, The Checker Board Model (CBM) is a new model of the nucleus that proposes that the protons and neutrons form a checker board pattern in the nucleus. This model assumes the two up quarks in the proton revolve around the down (dn) quark which is located in the center of the proton. Similarly the two dn quarks revolve around the up quark in the center of the neutron. This model assumes that the strong nuclear force is generated primarily from the close approach of the up quarks in the proton and the dn quarks in the neutron. CBM assumes the same frequency of revolution of quarks in the proton and neutron. This assumed structure plus the magnetic moments and masses of the proton and neutron, plus the binding energy difference of He(3) vs. H(3) gives some predictions of the size of the proton and neutron and the rest mass of the up and dn quarks and their speeds inside the proton and neutron. Avg radius proton = 0.519406 fm. Avg radius neutron = 0.6079394 fm. Rest mass up quark = 237.31 MeV. Rest mass dn quark = 42.392 MeV. Velocity up quarks in the proton = 0.848123 c. Velocity dn quarks in the neutron = 0.992685 c. Period of revolution = 1.283533 X10-23 seconds. Notice the de Broglie wavelength of the up quarks in the proton are equal to the circumference of their orbit in the proton.

NP01 56 A "Zero Space" Theory MARK MESSER, *Ford Motor Company* MESSER/WARHOLAK COLLABORATION, The term "Zero Space" describes the idea that every point in our local universe is occupied by the same field existing in two diffrent states or phases: a matter state and a "space" state. The matter state as "Condensed Space" and space is simply the free state of matter. A theory is discussed which describes the development of the matter state from the basefield, the micro structure of the basefield (The fabric of space time), and the relation of the field to light.

NP01 57 The Kaon Angular Distributions for Λ and Σ^0 Electroproduction at CLAS ROBERT FEUERBACH,* *Carnegie Mellon University* CLAS COLLABORATION, The electroproduction of kaons on protons has been studied with the CLAS spectrometer at Jefferson Laboratory as part of experiment 93-030. The K^+Y final states were selected by identifying the charged kaon with momentum and time of flight measurements, and then using the $p(e,e'K^+)$ missing mass to select the recoiling hyperon. From the data collected thus far with electron beam energies of 2.445 GeV and 4.045 GeV, the hyperon production spectra span a range of W from threshold to 2.5 GeV, Q^2 from 0.5 to 2.5 $(GeV/c)^2$, and most notably cover the full angular range in the hadronic center of mass frame. The preliminary kaon angular distributions for $K^+\Lambda$ and $K^+\Sigma^0$ final states as a function of Q^2 and W will be shown. It will be seen that the Λ and Σ^0 angular distributions are markedly different in given ranges of W and Q^2.

NP01 58 Determination of Nitrogen Concentration in Metallic Lithium* G. FOLTZ, *Colby College* D. J. DESIMONE, *University of Massachusetts Lowell* A. MITTLER, *University of Massachusetts Lowell* G.H.R. KEGEL, *University of Massachusetts Lowell* J. J. EGAN, *University of Massachusetts Lowell* At the University of Massachusetts Lowell Van de Graaff accelerator, neutrons are generated by bombarding thick metallic lithium targets with a 4-MeV proton beam. Lithium is purchased in the form of 2.25-gram ingots encased in sealed copper cartridges. Purchasing circumstances led us to acquire a 4-year supply of these cartridges. On occasion, this "aged" lithium was used, and a reduced neutron yield was obtained. Since nitrogen is the most abundant element in air, a contamination of lithium by nitrogen was considered, and a (p,γ) experiment was performed to determine the nitrogen concentration. We describe the experimental setup and show results.

*supported by NSF REU program at University of Massachusetts Lowell

NP01 59 Fiber-Based Neutron Spectrometer RICHARD A. CRAIG, *Pacific Northwest National Laboratory, Richland, WA 99352* MARY BLISS, *Pacific Northwest National Laboratory, Richland, WA 99352* PNNL has developed scintillating fibers that are sensitive to thermal neutrons. Because these fibers are thin, they present an enabling technology for several applications, including highly efficient neutron spectroscopy. The underlying concept is to arrange the fibers in an array of layers separated by moderating and absorbing materials whose characteristics have been chosen to optimize the desired bandwidth and resolution. Monte Carlo experiments have been performed to characterize the conceptual design and to determine concepts value as a tool for research and other applications. These results will be reported.

NP01 60 Solar cell array for nuclear spectroscopy with YRAST Ball* L. YANG, *WNSL-Yale University* R. KRUCKEN, *WNSL-Yale University* C.W. BEAUSANG, *WNSL-Yale University* R.F. CASTEN, *WNSL-Yale University* G. CATA-DANIL, *WNSL-Yale University* J.R. COOPER, *WNSL-Yale University* B. LIU, *WNSL-Yale University* J.R. NOVAK, *WNSL-Yale University* N.V. ZAMFIR, *WNSL-Yale University, Clark University* C. BARTON, *Clark University* Solar cells present a simple and cost-effective alternative for the detection of heavy-ions in nuclear spectroscopy experiments. Here we present an array of eight 1cm× 1 cm large solar cells, which was used in conjunction with the YRAST Ball array at the Wright Nuclear Structure Laboratory at Yale University. The cells were used for fission detection, fission suppression and the detection of inelastically scattered beam in various experiments. Their use in a Coulomb excitation experiment on ^{154}Sm enabled the measurement of the level lifetime with the Doppler-shift Attenuation Method (DSAM) of the first excited 0^+ state, which was found to be a β-vibrational excitation of the ground-state. We will present data on the performance of the cells, future developments of the array and some physics results of the YRAST Ball experiments.

*This work is in part supported by the DOE under grant numbers DE-FG02-91ER-40609 and DE-FG02-88ER-40417.

NP01 61 An Integrating Low-Energy Positron Spectrometer MARK SCHNEIDER, *Grinnell College Dept. of Physics* SARAH HODGES, *Grinnell College Dept. of Physics* KARMIN MAURITZ, *Grinnell College Dept. of Physics* CATHERINE NISBETT, *Grinnell College Dept. of Physics* MEGHAN O'CONNELL, *Grinnell College Dept. of Physics* The production of low-energy positrons from beta decay sources is important for a variety of applications, including surface studies and trapping of positrons for symmetry studies and attempts to produce anti-hydrogen. Positrons for these purposes come at energies of hundreds of keV from a radioactive source such as 22Na, and then are degraded and/or moderated in a solid. We have developed an integrating low-energy spectrometer specifically to enable us to inspect the low-energy tail of a degraded positron spectrum. This device uses a nearly solenoidal magnetic field to transport only the low energy positrons to a counting region where annihilation gamma rays are counted using coincidence techniques. The spectrometer is integrating in the sense that it accepts all low energy positrons with a transverse momentum below a cutoff determined by collimation and the magnetic field strength. Because no effort is made to do momentum determination within this momentum window, it is possible to create a device with nearly 2 pi acceptance solid angle. The longitudinal component of momentum can be inferred with a variable repelling voltage on the annihilation surface. We will present details of the design and construction of this device and the results from early tests.

NP01 62 Electron Deuteron Elastic Scattering in a Simple NN Potential with Excluded Spurious States: Non-relativistic Calculations. I.I. STRAKOVSKY, *Center for Nuclear Studies, Department of Physics, The George Washington University, Washington, DC 20052* S.B. DUBOVICHENKO, *Kazakh State National University, Almaty, 480121, Kazakstan* Simple analytic forms for the *NN* potential are useful for many nuclear physics applications. We present a new version of a simple *NN* potential which excludes the Pauli forbidden state coming from the short-range attractive part of the interaction. Parameters of *np* interaction have been chosen via a fit to the deuteron binding energy and the *np* scattering threshold behavior. The wave function of the potential has a node in the S wave and no node in the D wave. We find that our results reproduce all deuteron properties and are in good agreement with previous np results of NN Nijmegen-potential calculations below 350 MeV as well as the recent VPI&SU PWA determinations below 500 MeV. The observables form factors $A(Q^2)$ and B(Q), and the tensor polarizations T_{10}, T_{20}, T_{21}, and T_{22}, for *ed* elastic scattering are calculated over the kinematic range that is probed in Jefferson Lab measurements.

NP01 63 Revisit to Gamow Factor XING ZHONG LI, *Department of Physics, Tsinghua University** The conventional Gamow factor is valid for free-moving incident particles only. For resonance penetration via the lattice confined ions the penetration fac-

tor of the Coulomb barrier is θ^{-1}, while the Gamow factor is θ^{-2}. This theory answers Professor J.R. Huizenga's challenge of three miracles. The basic assumption(a (d+d) resonant state with a lifetime of 3 hours) is checked by the experiment data, and prediction is made for the future test in material science.

*Thanks to the support from NSF of China (Contract number 19645005),State Commission of Science and Technology, Fundamental Research Fund of Tsinghua University

NP01 64 The strong interaction shift in kaonic deuterium ROGER BARRETT, *University of Surrey* ANDRZEJ DELOFF, *Soltan Institute for Nuclear Studies* High precision measurements of kaonic hydrogen x-rays and also, for the first time, of kaonic deuterium are under way within the DEAR ($DA\Phi NE$ Exotic Atom Research) project using the e^+e^- storage ring at Frascati. The values of the strong interaction 1s level shift and width in kaonic deuterium cannot be simply predicted by relating them, via the Deser formula, to the K^-d scattering length because the latter is not known experimentally. It cannot be obtained, moreover by adding the K^-p and K^-n scattering lengths but involves the solution of a complicated multi-channel three-body problem. We give results of calculations of the kaonic deuterium strong interaction shift and width using ($N\bar{K}$, $Y\pi$) interaction which fits the available low-energy scattering data. The K^-d 1s shift comes out negative and both the shift and the width are estimated to be about 1 KeV. The 2p level width is predicted to be at least four orders of magnitude smaller than the 1s width. This information is of importance for the planned experiment as it indicates that most of the kaons should reach the lowest 1s level.

NP01 65 The pion-nucleus interaction and pionic atoms ROGER BARRETT, *University of Surrey* YOUCEF NEDJADI, *Oxford University* TIM COOPER, *University College of Fraser Valley* We have derived a relativistic impulse approximation to calculate the relativistic DKP pion-nucleus optical potentials, using the Duffin-Kemmer-Petiau (DKP) wave equation. These potentials use the time-like vector and scalar nuclear densities and relativistic pion-nucleon scattering amplitudes as input. The off-shell effects in pionic atoms result in different predictions by the DKP and Klein-Gordon equations (which predict the same effects on-shell). We give a systematic comparative analysis of our DKP relativistic pion-nuclear optical potential with all other previously proposed relativistic models, and with all the non-relativistic models available in the literature. We compare these models by looking at their respective prescriptions for the real and absorptive, S-wave and P-wave, isoscalar and isovector, pieces of the pion-nuclear optical potentials. We compare with experimental strong interaction level shifts and widths in pionic atoms over the whole of the periodic table using the DKP equation with our DKP pion-nucleus potentials.

NP01 66 A Toy Model for the Spatial Arrangement of Nucleons in Nuclei M.E. DE SOUZA, *Departamento de Física, UFS* It is not known how nucleons are spatially arranged in nuclei. This work proposes a toy model for the arrangement of nucleons in nuclei which agrees with the experimental data on dipole and quadrupole moments. With the model we are able to explain the absence of A=5 nuclei and the strange instability of ^{8}Be.

NP01 67 Proton Induced Fission Cross Sections for Heavy Nuclei in the 200 − 1000 MeV Energy Range A.A. KOTOV, L.A. VAISHNENE, V.G. VOVCHENKO, *Petersburg Nuclear Physics Institute, Gatchina, St. Petersburg, Russia* H.S. PLENDL, *Institute for International Cooperative Environmental Research Florida State University, Tallahassee, FL* I.I. STRAKOVSKY, *Center for Nuclear Studies, The George Washington University, Washington, DC* An accurate determination of the total fission cross sections of ^{nat}Pb, ^{209}Bi, ^{232}Th, ^{233}U, ^{235}U, ^{238}U, ^{237}Np, and ^{239}Pu induced by 0.2 to 1 GeV protons that are needed in nuclear waste transmutation studies and other nuclear physics applications of current interest is made in 100 MeV increments at an external beam position of the Gatchina 1-GeV proton synchrocyclotron. The beam intensity at that position is up to 1 μA but is decreased for this experiment to 10^5 to 10^6 s^{-1} so that it can be measured with a scintillation counter telescope, and the beam spot size varies from 1 to 2 cm^2. The targets range in thickness from 0.3 to 0.5 mg/cm^2. The fission fragments are detected in coincidence by two parallel plate avalanche counters located in front and in back of the target at a short distance from it, so that the solid angle acceptance for fission products is nearly 4π. The registration efficiency is about 100%. With this setup, fission cross sections of several target nuclei at 1 GeV were determined in previous work with an accuracy of better than 10% (see, e.g., L. M. Andonenko et al. J. Part. and Nuclei, **18**, 289 (1987)).

NP01 68 Charge Symmetry Violation in Pion Scattering from Light Nuclei V.V. BARU, A.E. KUDRYAVTSEV, V.E. TARASOV, *Institute Theoretical and Experimental Physics, Moscow, Russia* W.J. BRISCOE, K.S. DHUGA, I.I. STRAKOVSKY, *Center for Nuclear Studies, The George Washington University, Washington, DC* The theoretical and experimental status of charge symmetry violation (CSV) in the scattering of pions from deuterium and trinucleons is discussed. While not very noticeable in the pion-deuterium case, CSV seems to be more pronounced for the pion-trinucleon system. We present a theoretical formalism for CSV in terms of single- and double-scattering terms with Delta-mass splitting taken into account. Our theoretical results will be compared with the available experimental data. This work was supported in part by the George Washington University Center for Nuclear Studies Visiting Scholar Program and the Russian grant for Basic Research N 98–02–17618.

NP01 69 Hydrogen-like Atoms from Ultrarelativistic Nuclear Collisions* JOSEPH KAPUSTA, ÁGNES MÓCSY, *School of Physics and Astronomy, University of Minnesota* The number of hydrogen-like atoms produced when heavy nuclei collide is estimated for central collisions at the Relativistic Heavy Ion Collider using the sudden approximation of Baym *et al.* As first suggested by Schwartz, a simultaneous measurement of the hydrogen and hadron spectra will allow an inference of the electron or muon spectra at low momentum where a direct experimental measurement is not feasible.

*nucl-th/9812013

NP01 70 Photo-Production of the Delta with current quark masses GEORGE STROBEL, *Physics and Astronomy Dept., University of Georgia, Athens, Ga* The proton and Delta are three quarks assumed solely in the $(1/2^+)^3$ configuration, with angular momenta coupled to 1/2 and 3/2 respectively. The three body Dirac equation is solved with hypercentral linear and quadratic confining potentials, including all 8 components of the composite three quark wave function. With small quark masses, this model

reproduces the proton and delta energies, the proton rms size, axial charge, and magnetic moment. The lower components of the one quark wave function are $(1/2^-)$. These components have the orbital angular momentum needed for the E2 photo-production amplitude not to vanish, and contribute over 40 percent to the normalization. These are neglected in constituent quark calculations. With all 8 component wave functions, the E2/M1 ratio is mostly given by the first terms of $-j_2(kr)/2j_1(kr)=-0.05$. Assigning anomalous magnetic moments to quarks, the proton magnetic moment and the M1 photo-production amplitude can be simultaneously reproduced with a quark mass of order 1 MeV. About 20 percent of the M1 amplitude then comes from the quark anomalous magnetic moment interaction.

NP01 71 Experiments with Laser Trapped Radioactive ^{21}Na M.A. ROWE, S.J. FREEDMAN, B.K. FUJIKAWA, N.D. SCIELZO, P.A. VETTER, *UC Berkeley and LBNL* A laser trap for radioactive ^{21}Na ($t_{1/2}$ = 22 seconds) atoms has been constructed on-line at the 88'' cyclotron at LBNL. It is to be used to improve current beta decay measurements such as the parity violating asymmetry of spin-polarized nuclei and the electron-neutrino correlation. Our current focus is on recoil ion detection. Inside the trapping chamber we are installing a microsphere plate about 8 centimeters below the trapped atom cloud. Electric field rings will apply a constant electric field of about 500V/cm over the region from the trap center to the plate. When a ^{21}Na atom in the trap beta decays the daughter ion is accelerated into the microsphere plate and detected. Coincidence detection of both the ion and the beta from the decay will reduce our current background levels by discriminating against background from the vacuum chamber walls, allowing beta decay measurements to be made. The beta is detected with a plastic scintillator above the trap. The time between the essentially immediate hit of the upward going beta and the arrival of the accelerated ion at the microsphere plate gives information on their relative emission directions. From the timing information the beta-neutrino correlation can be extracted. For ^{21}Na the beta-neutrino correlation is mainly sensitive to possible scalar contributions to the weak interaction.

NP01 72 The Impact of Nuclear Reaction Rate Uncertainties on Evolutionary Studies of the Nova Outburst* WILLIAM RAPHAEL HIX, *JIHIR/UTenn/ORNL* MICAHEL S. SMITH, *ORNL* ANTHONY MEZZACAPPA, *ORNL* SUMNER STARRFIELD, *Arizona State* The observable consequences of a nova outburst depend sensitively on the details of the thermonuclear runaway which initiates the outburst. One of the more important sources of uncertainty is the nuclear reaction data used as input for the evolutionary calculations. A recent paper by Starrfield, Truran, Wiescher & Sparks (1998) has demonstrated that changes in the reaction rate library used within a nova simulation have significant effects, not just on the production of individual isotopes (which can change by an order of magnitude), but on global observables such as the peak luminosity and the amount of mass ejected. We will present preliminary results of systematic analyses of the impact of reaction rate uncertainties on nova nucleosynthesis. While the primary goal of our studies is to discern the extent to which theory is discrepant from observations, we will also determine the relative importance of changes in individual reaction rates and provide guidance in the selection of reactions for further experimental study.

*Research supported by the U.S. Department of Energy under contract DE-AC05-96OR22464 with Lockheed Martin Energy Research Corp.

NP01 73 Polarized Parity Violating Electron Scattering in ^3He and ^3H MICHAEL BARNETT, *Florida International University* STEPHAN MINTZ, *Florida International University* GEORGE GERSTNER, *Florida International University* MOHSEN POURKAVIANI, *Florida International University* We obtain the asymmetry,A, for a range of incident electron energies from 0.5 GeV to 6.0 GeV for elastic scattering on ^3He and ^3H. We also obtain the corresponding figures of merit. We show that the asymmetry for these nuclei have substantial structure. We also show that contributions from the weak strange quark current induce large changes in the asymmetry in the region of the first maximas and minimas which might be measureable under favorable circumstances. We also discus the relationship between the two reactions considered here and show that measurements of both at the same q^2 would enable the weak current form factors to be determined at energies not otherwise available.

GFC: PRECISION MEASUREMENTS AND FUNDAMENTAL CONSTANTS

NP01 74 The Deuteron Binding Energy and the Neutron Mass ERNEST KESSLER, MAYNARD DEWEY, RICHARD DESLATTES, ALBERT HENINS, *National Institute of Standards and Technology, Gaithersburg, MD* HANS BÖRNER, MICHAEL JENTSCHEL, CHRISTIAN DOLL, HUGO LEHMANN, *Institut Laue-Langevin, Grenoble, France* A new value for the deuteron binding energy of $S(d)$ = 2.38817007(42) × 10^{-3} u is reported based on an absolute wavelength determination of the 2.2 MeV n-p capture gamma-ray using a crystal diffractionspectrometer. A previous crystal diffraction measurement of the deuteron binding energy has an uncertainty 5 times larger than this result. A new more precise value for the neutron mass m_n = 1.00866491637(82) u is obtained by summing this binding energy and the ^{2}H - ^{1}H mass difference. The uncertainty of the neutron mass has been reduced by ≈ 2.5 and the uncertainty contributions are 0.42 × 10^{-9} u and 0.71 × 10^{-9} u from the binding energy and mass spectroscopic measurements, respectively.

NP01 75 The Fundamental Constants and the Inertial Field MARTIN GIBSON, The constants, G, c, h, and e can be derived from one natural constant, tav, the inertial constant, (herein ♡ due to no LaTeX support for tav) in light of an expanding inertial field (quantum vacuum) of variable inertial density, ρ. Particles are 3D waves, not points. G, B and E fields are density fluctuations propagating from particle motion. Functionally, where r, m, ω, γ and α are customary: m = f(ρ), r = f(m) = ♡/m, ♡ = $\gamma(-m^2)$ dr/dm (also = $1/\gamma$ $(-r^2)$ dm/dr), ω = g(r) = c/r = g(f(m)) = mc/♡, c = $1/\gamma$ $(-r^2)$ dω/dr = ♡ dω/dm, h = $2\pi\heartsuit^2$ dω/dm, e^2 = $-4\pi\epsilon_0\alpha(\heartsuit\ 1/\gamma^2 r^4)d\omega^2/dr^2 = -4\pi\epsilon_0\alpha(\heartsuit^3)d\omega^2/dm^2$ (= $-\alpha'\heartsuit^2 d\omega^2$, where ϵ_0 = $dm^2/\heartsuit$ and $\alpha' = 4\pi/\alpha \approx 1/(2\pi\sqrt{3})$), e = $i\alpha'^{1/2}\heartsuit\, d\omega$, G = $[(r_a^2/\heartsuit)^2/(\pi/3)]\ r_a{}^2 d\omega^2$, (where r_a = avg nucleon radii, dω → 0) = $[(r_a{}^2/\heartsuit)^2/(\pi/3)]\heartsuit\ d\omega^2\ (-1/\gamma)$(dr/dm), And P = $-\heartsuit r\ d\omega/dr = (\heartsuit^2\gamma/r)\ d\omega/dm$, E = $(\heartsuit^2 r)\ (d\omega/dm)(d\omega/dr) = (1/\gamma\heartsuit\ r^3)\ d\omega^2/dr^2$, Schrodingers: E = $(\heartsuit r^2/2)\ d\omega^2/(dr^2/n^2) = (n^2/2)\ (\gamma\heartsuit/r)\ (-1/\gamma\ r^2\ d\omega/dr)^2$, Gravitation, where n_m and n_d = qty of fundamental units: $F_g = [(n_{m1}n_{m2})/(4\pi n_d^2/12)][h^2/4m^2L^2] = [(M_1M_2)/d^2]\ [(r_a{}^2/\heartsuit)^2/(\pi/3)]\ \heartsuit\ d\omega^2\ (-1/\gamma)$(dr/dm). Inertial constant: ♡ = ħ/c = 3.517672286e-43 kg-m. The Quanta (dω/dm = constant): Momentum-♡ dω, Force-♡ d

ω^2, Action($\hbar$)-$\heartsuit^2$ dω/dm, Energy-$\heartsuit^2$ (dω/dm) dω. Strong and weak interactions and electron/neutron mass ratio can be derived in light of the above, given geometric constraints.

NP01 76 Frequency Stabilization of rf-Pumped Me-Ne/$^{127}I_2$ Laser ANATOLIY NEGRIYKO, OLEXIY BOYKO, LEONID YATSENKO, *Institute of Physics National Academy of Sciences, Kyiv, Ukraine* For practical realization (mise en pratique) of definition of metre as the length which light pass in vacuum during 1/299792458 sec Comité International des Poids et Mesures in 1997 recommended twelve standard wavelengths. The wavelengths of He-Ne laser stabilized by saturation absorption $^{127}I_2$ molecule are very important for practical application. The very first He-Ne lasers have been pumped by longitudinal rf-discharge. Due to essential imperfections these lasers were replaced by lasers pumped by dc-discharge. Now the He-Ne lasers pumped by transversal rf-discharge are developed. There are some advantages of these lasers, main of them is lower amplitude noise level (3-4 times comparing to dc-pumping). We study the frequency stability of rf-pumped He-Ne/I_2 laser (632,8 nm). It was showed that the frequency stability of rf-pumped He-Ne/I_2 lasers is higher then one of lasers pumped by dc-discharge. The frequency unstability of rf-pumped He-Ne/I_2 lasers is $2.8 \cdot 10^{-12}$ at the average time 10 sec. The comparision of rf-pumped laser with iodine stabilized dc-pumped He-Ne laser of State Primery Length Standard of Ukraine were performed. The averaged frequency difference over d,e,f,g absorption components of the iodine molecular transition 11-5, R(127) was $\nu_{rf} - \nu_{dc} = 1.2$ kHz, standard deviation 3.2 kHz.

NP01 77 Hyperfine Structure Measurements of the 4d2D3/2,5/2 Levels of Gallium 69 and 71 S.J. REHSE, *Colorado State University* W.M. FAIRBANK JR., *Colorado State University* S.A. LEE, *Colorado State University* We have determined the hyperfine structure of the 4d2D3/2,5/2 levels of 69,71Ga. The 4p2P3/2 - 4d2D3/2 (294.50 nm) and 4p2P3/2 - 4d2D5/2 (294.45 nm) transitions were studied by laser induced fluorescence in an atomic Ga beam. The hyperfine B constants for the 4d states are determined for the first time. The A constants are measured with a greater accuracy and are found to have the opposite sign from literature values. Improved values of the isotope shifts of both transitions are reported. The relevance of this work to the optical manipulation of gallium will also be discussed.

NP01 78 ^{133}Cs (I=7/2) $6^2P_{3/2}$ Hyperfine Structure Measurements VLADISLAV GERGINOV, CAROL TANNER, *University of Notre Dame, Department of Physics,225 Nieuwland Science Hall, Notre Dame, IN 46556-5670** The experimentally studied hyperfine structure (HFS) can be compared with the results from Hartree-Fock and many-body perturbation theories which are important to interpretation of parity nonconservation (PNC) in atomic systems. The HFS of ^{133}Cs $6^2P_{3/2}$ level is being intensively investigated. It may be possible to determine the magnetic octupole interaction contribution to HFS energy (frequency) differences by measuring the splittings with an accuracy of 1kHz or better. We propose to lock two frequency stabilized 852nm diode lasers to two different HFS levels of $6^2S_{1/2}$-$6^2P_{3/2}$ transition and mix their frequencies with a photodiode to determine the frequency difference between the HFS levels. To obtain a Doppler-free spectrum the laser beam will cross a collimated thermal atomic beam at a right angle. In this case the spectrum is Doppler-free with natural linewidth of the transition (5MHz).

NP01 79 Laser-induced continuum structure in He* KLAAS BERGMANN, THOMAS HALFMANN, LEONID YATSENKO, MOSHE SHAPIRO, BRUCE W. SHORE, *Fachbereich Physik der Universität, D-67653 Kaiserslautern, Germany* We report the observation of laser-induced continuum structure (LICS) in the photoionization of helium out of the metastable singlet state. The same region of the continuum is reached from the 2s and 4s states by 294 nm and 1064 nm radiation, respectively. We observe in this otherwise unstructured continuum a strong and spectrally sharp resonance (the narrowest being 0.6 GHz), showing both enhanced and diminished ionization (by as much as 70%). The latter is due to population trapping associated with LICS. We also show the effect of dynamic Stark shifts upon the LICS profiles. A theoretical model gives quantitative agreement with the experimental results for a wide range of intensities.

NP01 80 Enhanced chaotic positron accumulation by sequenced resonant kicks R.S. CONTI, *The University of Michigan* BITA GHAFFARI, *Rice University* We report on improvements to the Michigan positron accumulator resulting from an understanding of the chaotic nature of the long term trapping mechanism [1]. In the previous incarnation, a brute-force method was used to give the positrons large radial kicks each time they execute an axial orbit. In the improved version the chaotic action of a synchronized series of small kicks efficiently transfers the positrons to low-loss orbits where they accumulate for later extraction. [1]B. Ghaffari and R.S. Conti Phys. Rev. Lett., 75 3118 (1995)

AAPT: AMERICAN ASSOCIATION OF PHYSICS TEACHERS

NP01 81 What we have learned from restricting the use of calculators in general physics ROGER ROCKEFELLER,* *Utica College* Over the past several years, I have restricted the use of calculators in my college-level, non-calculus, general physics courses. The goal was to improve the ability of students to handle the arithmetic and algebraic requirements of the class. Student resistance is significant at the beginning of the semester, but diminishes with time. What has been revealed, however, is an inherent weakness in performing calculations by many of our students, including some who have taken high school calculus. This is evidenced by the type of arithmetical errors made on the simplest of problems, and it suggests that an over-dependence on calculators has robbed our students of fundamental computational skills that, in turn, may limit mathematical reasoning.

*Department of Physics

NP01 82 The effect of arithmetic skills on success in general physics MARIAROSA ALLODI,* *Utica College* Freshman students at our college must take a mathematics placement examination which also serves as a diagnostic tool. A comparison of performance on the arithmetic section of the test, with grades in our non-calculus, general physics classes, demonstrates the correlation between an understanding of arithmetic operations, and, success with physics, regardless of the number and the level of the high school courses that have been successfully completed

*Utica College

NP01 83 Atmosphere, Weather, and Baseball: Does the Ball Really Fly Farther at Denver's Coors Field? CLYDE ZAIDINS, *University of Colorado at Denver* FREDERICK CHAMBERS, *University of Colorado at Denver* BRIAN PAGE, *University of Colorado at Denver* From its inauguration in 1995, Coors Field has gained national notoriety as a launching pad of historic proportions. Over the 1995- 1997 seasons, the Denver ball park led all major league parks in total home runs and home runs per at bat – both by a very wide margin. Most observers, physicists and baseball people alike, assume that more home runs are hit at Coors Field due to the effect of low air density at higher elevations; compared to the league average adjusted for the actual elevation of each ball park, the ball should travel 9.3 percent farther in Denver. Our research tested this assumption through an analysis of fly ball distance data for all National League ballparks for the years 1995-1997. Our results show that the ball travels only 6.5 percent farther at Coors Field compared to the average for all other National League ball parks. When this comparison is adjusted to reflect actual field dimensions, the difference is just 2.8 percent. In order to explain these unexpected results, we set up two weather monitoring stations inside Coors Field during the 1997 season. Measurements taken included temperature, relative humidity, barometric pressure, and wind as recorded by equipment that provides three-dimensional modeling of air flow. The initial results of our micro-meteorological analysis indicate that of the measured variables, wind – especially the vertical component – is most strongly correlated with shorter fly ball distances in Coors Field. We have constructed a computer model which permits a variation in air density and wind velocity as well as the launch speed and angle for the trajectory of fly balls.

NP01 84 Using a Synchrotron Light Source to Probe Brain Mechanisms JANE KRAKOWER, *University of South Florida* This paper suggests that synchrotron light activates polarized brain cells which, because of membrane polaribility can receive light. It explains how Synchrotron radiation can penetrate and activate brain cells and thus serve as an excellent probe of brain mechanism. Wavelengths within the broad range of Synchrotron Light have the same dimensions as molecules, atoms, and solids in brain cells, and with the correct polarization can allow the light to pass through brain membranes, rather than be absorbed. This theory describes how outer influences can effect intellectual thought processes and brain activity because Superlattices and the geometry of brain membrane surfaces permit coherent quantum transmission.

NP01 85 An Automatic Impedance Measurement System for Detecting Superconducting Transitions via Magnetic Screening DJALMA MEDEIROS, *Faculdade de Engenharia, Universidade Sao Francisco, Itatiba-SP, 13251-900, Brazil* CLOVIS E. M. OLIVEIRA, *Faculdade de Engenharia, Universidade Sao Francisco, Itatiba-SP, 13251-900, Brazil* Using a microcomputer with an A/D and D/A interface board, we have developed an automatic impedance meter for detecting the critical temperature of superconductor ceramics. The superconductive sample is introduced in a coil and the set is placed in a simple cryostat. Our system measures the temperature of the sample using a commercial integrated circuit sensor and can change the sample temperature in steps of 0.5K from 77K to 350K. It can also calculate the coil's impedance generating a sinusoidal signal applied over the coil and measuring the current and the voltage of the coil. The impedance is composed of a real component (related to the resistance) and an imaginary component (related to the reactance). The coil's reactance change dramatically at the phase transition of the sample and from this change we can determine the critical temperature. All the process is controlled by software based on LabVIEW. This is a good and inexpensive apparatus for general demonstration of superconductor transitions and it is also useful to introduce undergraduate students to the basic research.

NP01 86 Development of Laboratories to Supplement Moore's IUPP-Based "Six Ideas" at Smith College: I. Mechanics and Thermodynamics D. A. WEINBERGER, *Dept. of Physics, Smith College* N. FORTUNE, N. EASWAR, J. PFABE, *Dept. of Physics, Smith College* In this pair of poster papers we present a series of laboratories developed at Smith College to be used with Thomas A. Moore's "Six Ideas That Shaped Physics" model. We discuss several pedagogical issues, such as balancing minilabs and project labs, correlation of labs with class topics, and evaluation of students' lab work. The first semester laboratories deal entirely with mechanics and are well integrated with the course material. We make extensive use of sonar rangers, as well as camcorders and freeze-frame VCR's for video data acquisition and qualitative analysis. We will demonstrate video analysis of projectile motion of extended objects, momentum conservation in collisions, and energy conservation in oscillating spring systems. Similar techniques can be used for more extensive investigations, e.g., filming apparent weight changes during an elevator ride and determining the total distance traveled. We also discuss a series of thermodynamics minilabs and illustrate the counting-of-microstates software used in conjunction with the course.

NP01 87 Development of Laboratories to Supplement Moore's IUPP-Based "Six Ideas" at Smith College: II. Electricity, Magnetism, Waves, and Optics D. A. WEINBERGER, *Dept. of Physics, Smith College* N. EASWAR, N. FORTUNE, J. PFABE, *Dept. of Physics, Smith College* The second semester laboratories focus on electrical fields and circuit analysis, a series of minilabs on magnetic phenomena, and quite extensive investigations of waves and interference and diffraction phenomena. The lab topics are less well correlated with course material than in the first semester, due to the large amount of time devoted in class to electricity and magnetism and the relatively brief treatment of waves and optics (in Unit Q). We use lab work to explore some material not covered in the course; this also helps to better synchronize lectures and laboratories. For example, we spend 1-2 lab periods on geometrical optics; a set of minilabs on standing waves; and a set of minilabs exploring forced oscillations and resonance in a variety of physical systems. We also spend one lab period having students assemble the components of an open-bore He-Ne laser and having them explore its transverse mode patterns. We will demonstrate this apparatus and discuss more extensive investigations which can be done with the laser.

NP01 88 Educational Computer Program for Accurate Visualization of Electron Transport in Noble Gases J.A.S. BARATA, *Departamento de Fisica, Universidade da Beira Interior, Portugal* C.A.N. CONDE, *Departamento de Fisica, Universidade de Coimbra, Portugal* The transport of electrons in noble gases under the influence of an electric field was the subject of recent research work using a tri-dimensional Monte Carlo tech-

nique with a set of accurate integral and differential cross-sections, leading to results (drift velocities, diffusion coefficients, electroluminescence yields, etc) in very good agreement with experiments [1]. In the present work we apply these techniques to the development of an educational computer program that allows the accurate visualization of detailed movement of individual electrons in a noble gas (xenon) under variable conditions of pressure and electric field intensity. The Fortran program running on Linux in a portable Pentium computer will be demonstrated. It allows the student to visualize in the display the electrons drifting in the gas and to study the physics of the processes involved. [1] T.H.V.T-.Dias and F.P. Santos, A.D. Stauffer, C.A.N. Conde, Monte Carlo simulation of x-ray absorption and electron drift in gaseous xenon, Phys. Rev. A, 48 (1993), 2887.

NP01 89 ESFERAS: Radiation Hydrodynamics Through a web-based computer experimentation* FELIX AGUIRRE, *Laboratorio de Física Teŕica, Universidad de Los Andes, Mérida Venezuela* JAVIER D. GUTIERREZ, *Centro Nacional de Clculo Cientfico Universidad de Los Andes, Mérida Venezuela* HÉCTOR HERNÁNDEZ, *Centro Nacional de Clculo Científico Universidad de Los Andes, Mérida Venezuela* LUIS A. NÚÑEZ, *Centro Nacional de Cálculo Científico, Universidad de Los Andes, Mérida Venezuela* It is the purpose of this poster to present an application, ESFERAS, oriented to understand better the of general relativistic stellar collapse through computational experimentation. This algebraic-numeric-visual web based environment is to intended to provide undergraduate and graduate students with some physical insight of very complex phenomena closely related to research topics. ESFERAS is based on a general method proposed by L. Herrera, and Collaborators (L. Herrera, J. Jiménez and G. Ruggeri *Phys. Rev. D* **22**, 2305 (1980)). Besides regularity conditions, models are only restricted by a heuristic assumption relating density, pressure and radial matter velocity. This *ansatz*, guided by very solid physical principles, reduces the problem of solving Einstein Equations to a numerical integration of a system of ordinary differential equations for quantities evaluated at the surfaces (shocks and/or boundaries). Through a library of models, the user can visualized several collapsing configurations. It is also possible to select the corresponding field equations regarding the fluid to be consider and in two limits for the radiation transport: *free streaming out* and *diffusion*. As possible fluids, the system have: isotropic, anisotropic, viscous, and charged, and any combination of them. New models can be worked out using algebraic modules written in REDUCE or MAPLEV which allows the user to calculate and to write down subroutines starting from a ''seed'' static equation of state.

NP01 90 Computational Physics: a Course, a Book, and Web Tutorials* RUBIN H LANDAU,† *Physics Department, Oregon State University, Corvallis OR 97331* A university level course in Computational Physics has been developed, a book based on this course (Computational Physics, Problem Solving with Computers, Wiley) has been published, and an extensive collection of multimedia, interactive Web tutorials which complement and extend the book have been developed. This part of an experiment in academic–commercial publishing in which Wiley publishes a traditional book while we maintain links to free Web tutorials. A table of contents for all these materials with links to the Web materials is at www.physics.orst.edu/~rubin/CPbook/. A description of the course and it setup is at http://goophy.physics.orst.edu/~ph465/. The educational material is in the form of individual projects which follow a problem-solving paradigm for a very wide class of problems employing physical, mathematical, and computational techniques. As a consequence of having to interact with the material, it becomes part of the personal experience of the students. The Web materials were developed by the Physics group of NACSE (an NSF Metacenter Regional Alliance). Some are directly related to the course, while others are more general, dealing deal with visualizations, HPC library use, PVM, and, Coping with Unix. Our emphasis is to exploit Web technology to better teach about and improve the use of HPC resources in science.

NP01 91 Developing Interesting Interactive Exercises as a Supplement to First-Year Physics Lectures LAUREEN G. REED, *Saginaw Valley State University* ERIN A. GAJEWSKI, *Saginaw Valley State University* We have developed several interactive Macintosh-based exercises to supplement lecture material on a variety of topics in our first-year calculus and non-calculus physics courses. We describe the exercise construction process and present sample screens from two of the exercises.

NP01 92 Physics - Concepts and Models: A Web-based Physics Learning and Teaching Tool. DAVE J. AUSTEN, *University of Alberta* WYTZE BROUWER, *University of Alberta* HANS LAUE, *The University of Calgary* BRIAN E. MARTIN, *King's University College, Edmonton, Alberta* Physics - Concepts and Models: A Web-based Physics Learning and Teaching Tool. We present an overview of Physics - Concepts and Models (PCAM). PCAM is aimed at helping students understand physics concepts, starting from student ''alternative conceptions.'' PCAM gets students to test and modify their understanding of physics in a constructivist manner by taking advantage of the computer medium's strength that makes interactive simulations possible. The program is Web-based and written in Java and HTML which allows it to be platform-independent and customizable. Instructors are able to select and order the material or add new material as needed for a given course or in-class presentations. The intuitive navigation system will automatically display such re-arrangements to the users. By being able to customize the software, instructors will find it easier to integrate it into their courses. At the same time, students will appreciate having software arranged by their instructor. The PCAM project is funded by the Province of Alberta through a Learning Enhancement Envelope grant.

NP01 93 A Universal Physics Modeling Environment in Java THOMAS FUHRMANN, *Uni Heidelberg, Germany* D. W. HEERMANN, *Uni Heidelberg, Germany* Computer simulations of physical processes have long provided scientists with valuable insights into their field of study. Its benefits in science education, however, are still masked by the complicated and counterintuitive handling of the necessary numerical algorithms. Although computer animations successfully allow for the interactive illustration of a specific topic, arbitrary experiments with various physical objects are mostly impracticable. On the other hand, our teaching experience shows that it is especially such unrestricted and creative examination of new concepts that greatly boosts the motivation of students and improves their learning results. In order to provide such unrestricted experiments in our TeleTeaching and

HomeLearning scenarios, we developed a universal physics modeling environment in Java. Here students can freely combine predefined physical objects like springs, ropes, charged spheres and observe the resulting physical effects. Furthermore they can easily define new objects, e.g. a magnet, by describing the physical interactions without having to know the mathematics underlying the simulation.

NP01 94 Assessment of In-Service Workshops on Students' Learning CHRISTIE A. DELZER, *Moorhead State University* VIJENDRA K. AGARWAL, *Moorhead State University* Moorhead State University has conducted in-service Sharing Science workshops for nearly a decade to improve teachers' knowledge with the goal of better student achievement in physical sciences. The workshops were assessed by participants for instructional effectiveness each year. Additionally, an assessment project was initiated last year to measure students' learning at all levels in one school district in rural Minnesota. The assessment procedure consisted of interviews with teachers, a questionairre completed by teachers, and a set of tests taken by their students. The tests were designed to assess specific analytical skills along with content knowledge. This presentation focuses on the kinds of tests that were designed and why, and the results which are not as conclusive as anticipated. Based on experiences from the first set of data, the tests were redesigned and are being administered again. Included in the presentation is the progress to-date and a discussion of what has been learned.

NP01 95 Teaching Fundamental Physics Concepts through Tricky Problems BORIS M. KORSUNSKY, *Thayer Academy* In this presentation, I will discuss the use of unusual, Olympiad-style problems in teaching certain fundamental, yet frequently overlooked concepts, such as: Physics Models vs. Physical Reality; Frames of Reference and Relativity of Motion; Omnipresence of Simple Harmonic Motion. Most of the problems are taken from my book "Challenging Problems for Physics," which I have been using with my AP Physics classes for several years. In addition, I hope to make my colleagues aware of the necessity to use non-conventional, creative problems in classroom teaching. Problem-solving can be made more enjoyable and instructive if these "braintwisters" become regular at classroom discussions.

NP01 96 The Earth's Rotational Period and the Origin of Species BRIAN R. TAYLOR, *Slippery Rock University* KEVIN D. TAYLOR, *Shippensburg University* All organisms (bacteria, plants, fungi, and animals) appear to have an internal biological clock which governs circadian rhythms. This clock is an internal mechanism which measures time in the living organism independent of environmental cues. The clock of each species has its own daily cycle length which is close to, but not exactly, 24 hours. It has been suggested that different species with the same daily cycle length may have descended from a common ancestor. An alternative explantion may be that these species originated approximately at the same time, not necessaily from a common ancestor. More specifically, we hypothesize in this paper that the internal daily cycle length of each species was determined (excluding gene mutations) at the time the species originated and its value corresponds to the earth's rotational period at that time – a period which is increasing by about 22 microseconds per year. For example, under this hypothesis, squirrels, which have a 23 hour biological clock, originated 164 million years ago and plants with 22 hour biological clocks originated 316 million years ago.

NP01 97 High Zeeman Field Narrowing of the NMR Peaks of Spin 1/2 Nuclei Coupled to Quadrupolar Nuclei: ^{31}P NMR Widths as a Probe of the RbH_2PO_4(x)-$NH_4H_2PO_4$(1-x) Proton Glass RIQIANG FU, *NHMFL* NARESH DALAL, *Chemistry Dept. FSU* The understanding of the microscopic origin of the electric analog of the spin glass behavior by a random mixture of a single crystal of a ferroelectric and an antiferroelectric lattice is one of the areas of active research in phase transitions. In particular, this opens up a new area in solid state physics wherein one can compare the fundamental similairities and differences between a behavior of the magnetic dipoles versus electric dipoles. It has been well established that in a certain composition range, the mixed crystals of the RbH_2PO_4 (RDP) and $NH_4H_2PO_4$ (ADP) exhibit a spin glass behavior, but the details of the underlying mechanism are still not fully understood. In order to obtain new clues to this phenomenon, we have initiated a systematic study of the utility of the high field NMR techniques. We have carried out ^{31}P NMR measurements on a series of $R_xA_{1-x}DP$ compositions. It is found that compared to Zeeman field at 7T, those at 14T yield improved NMR resolution in the case of the Rb dominated compositions. This opens up a new avenue for studying these proton glasses. The possible cause of this high field-induced NMR line-narrowing will be discussed, together with the interpretation of the data in terms of the spin glass mechanism.

NP01 98 Miniaturized High Resolution Thermometer for use in Earth-Orbiting Low-Temperature Physics Experiments* DMITRI A. SERGATSKOV, BEVERLY J. KLEMME, STEPHEN T.P. BOYD, ROBERT V. DUNCAN, *University of New Mexico* PETER K. DAY, *Jet Propulsion Laboratory* We present performance data on a prototype of a miniaturized High Resolution Thermometer (mHRT) to be used in upcoming flight experiments, such as Critical Dynamics in Microgravity (DYNAMX). This mHRT utilizes a magnetic alloy as its sensing element, and has a mass of approximately 4 grams. The design is optimized to minimize the effects of cosmic radiation once on orbit, and to withstand mechanical launch loads. On earth, one such thermometer has demonstrated $0.4nK/\sqrt{Hz}$ noise with a time constant of less than one second, and a drift rate of less than $80fK/s$.

*This work has been supported by NASA through Microgravity Research Division.

NP01 99 Trapped positrons for materials analysis* R.G. GREAVES, *First Point Scientific, Inc.* C.M. SURKO, *University of California, San Diego* Significant progress has been made in accumulating large numbers of room-temperature positrons in a Penning trap (e.g., $> 10^8$ e^+ in a few minutes from a radioactive source and rare-gas moderator).[1] These collections of positrons are useful for a variety of scientific and technological applications. For example, by releasing the trapped positrons in a controlled manner, it is possible to form a beam with a very narrow energy spread (< 20 meV).[2] While this beam is magnetized in the Penning trap, it should also be possible to extract the positrons from the field, remoderate, focus, and bunch them to create a state-of-the-art pulsed electrostatic beam. The capture efficiency of the trap is

remarkably high (> 30%) and losses in the trap are small (annihilation time > 60 s), so that high e^+ throughput can be obtained. We discuss the creation and potential uses of such beams for materials analysis techniques now existing and under development.

NP01 100 Positron and Positronium Annihilation in Natural Opals: Novel Approaches to Analysis URBAN-KLAEHN M. JAGODA, C.A. QUARLES, *Texas Christian University** Natural opal samples have been examined by use of the Positron Annihilation Techniques: Lifetime (LT) and Doppler Broadening Spectroscopy (DBS). Additionally all solid samples have been examined under the Scanning Electron Microscope. Opal samples were in different maturation stages, amorphous and powdered: Opal - A, partly crystallized: Opal-CT , Opal-VV from Virgin Valley, quartz altered from opal sample (Q-O) and completely crystallized Quartz Aventurine (Quartz-Av) sample. In all opal samples two long lifetimes with the values: 2 ns and 10-50 ns were detected with the intensities of 10-17% have been attributed to the pick-off otho-positronium annihilation in crystals of cristobalite and tridymite (2 ns) and in the three-dimensional tektosilicate framework structure (10-50 ns). By use of the DBS quotient analysis as well as the derivative analysis the distinction between the self para-positronium annihilation (dominant process in opal samples) and valence electron annihilation (dominant process in rocks with low microporosity) has been detected. From the lifetime values we were able to calculate the average size of the micropores, their distribution and correlate the positron annihilation parameters with the stage of maturation of opals from the early amorphous stage through the formation of cristobalite and tridymite crystals to the completely crystallized quartz structure.

*Dr. G. Salaita from the Chevron Petroleum Technology Co.

NP01 101 Micromachined Tip with Subwavelength Metal Aperture for NSOM and SPM Application M.Y. JUNG, I.W. LYO, *Atomic-scale Surface Science Research Center, Yonsei Univ. Seoul, Korea* S.S. CHOI, *Dept. of Physics, Sun-Moon Univ. Ahsan, Chungnam, Korea* Y. KUK, *Dept. of Physics, Seoul National Univ.* Micromachining of a nanoscale Si tip for near field scanning optical microscopy(NSOM) and scanning force microscopy(SFM) has been described. Various micromachining methods have been performed in order to have a metal aperture with radius less than /2. Apertures provided with less than /2 and hollow tips would provide a suitable probes for both NSOM and SFM. The nanosize (10nm>) Si tips were fabricated.A silicon nitride and a metal layer have been deposited on the Si-tip.The procedures such as field evaporation and PR removal technique have been performed in order to get a subwavelength aperture on the tip suitable for NSOM and SPM.

NP01 102 A Digital Correlation Spectrometer for Plasma Research* N.H. BROOKS, *General Atomics* D. FINKENTHAL, *Palomar College* T.K. JENSEN, *General Atomics* N. NAUMENKO, *IMAPH* S. TUGARINOV, *TRINITI* Combining the correlation spectrometer concept with modern digital techniques has resulted in a novel grating spectrometer with unique advantages for measurements in noisy plasma systems and in discharges with intense continuum background. The instrument, dubbed an "active" spectrometer, incorporates digital control of an oscillating component (a mirror) and phase-locked digital recording of the intensity profile within the narrow spectral domain defined by the mirror oscillation. Flexible choice of oscillation frequency permits measurement in a quiet region of the noise spectrum. Reference waveforms acquired with the same instrument can be stored and later used to deconvolute a more complex spectrum. The use of multiple detector/slit combinations along a Rowland circle makes the spectrometer sensitive to specific atomic elements. Application of the active spectrometer to a partial pressure diagnostic on a tokamak fusion device illustrates some of the unique characteristics of this invention.

NP01 103 Diffuse x-ray scattering from sputtered multilayers at large in-plane Q's* A.T. MACRANDER, *Argonne* R.L. HEADRICK, *Cornell* C. LIU, *Argonne* Synchrotron x-ray studies of the diffuse scattering for both correlated and uncorrelated roughness were obtained for length scales down to 5 nm. The data require a logarithmic interface roughness correlation function.

*DOE contract No.W-31-109-ENG-38 and NSF award No.DMR-9311772

NP01 104 Neutron three-axis spectrometry with focusing monochromators and position sensitive detection MIHAI POPOVICI, ALEXANDRU STOICA,*WILLIAM YELON, RONALD BERLINER, *MURR* Bent perfect crystals show promise in neutron three-axis spectrometry with position sensitive detection (PSD). Usual sequential scans may be replaced by simultaneous PSD scans along any given direction in the scattering ($h\omega$,Q) plane. The direction is controlled by the curvature of the analyzer crystal. In focusing instruments with thin silicon wafers the achievable resolution, expressed in angular terms, is of about 0.03 deg. In conventional three-axis instruments this would require Sollers of about 1 minute of arc divergence. The corresponding resolutions in energy transfer are in the 10 to 100 microeV range. PSD spatial resolutions of about 0.2 mm will be required, though, to achieve such resolutions. With PSD analysis a new kind of focusing exists, that allows the thickness of the analyzer crystal to be increased with gains in intensity at no loss of resolution. Experimental results are presented, confirming that under the right conditions a multilamella analyzer looks like a single bent wafer, the individual curves of many wafers having been put together. Were not for this possibility, usual sequential and simultaneous PSD scans would have been equivalent as to the rate of data collection. Because of it, an intensity gain by the number of lamellae (15-20) is achievable. This is in addition to the intensity gain from "normal" focusing, which our recent experiments (Physica B 241-243, 1998, 216-218) have shown to range from 10 to more than 100. Supported by DOE grant FG02-96ER45599.

*On leave from NIMP Bucharest, Romania

NP01 105 The scales of fluctuations in stochastic media which produce Doppler–like Wolf shifts P. SCOTT CARNEY, *Dept. of Physics and Astronomy, University of Rochester, Rochester, NY* The rate of fluctuations and the magnitude of the spatial correlations required to generate Doppler–like Wolf shifts of spectral lines on scattering from stochastic media are considered for a class of model media.

NP01 106 Comparison between Kinematical and Dynamical Calculations of Rocking RHEED Intensities SHENG WEN, J.A. CARLISLE, *Virginia Commonwealth University* Kinematical and dynamical calculations are two important tools for the quantitative analysis of RHEED intensities. Dynamical models are considered to be generally superior to kinematical ones when performing RHEED rocking curve analyses. However, several recent studies have reported the successful use of this latter approach for surface structure determination. In our research, numerical methods are being developed for both kinematical and dynamical calculations of RHEED intensities. Comparison is made between these two methods based on their application to several well-known reconstructed surface systems, including the clean Si(111)-(7× 7) and Si(100)-(2× 1) surfaces. Critera for selecting the appropriate method are proposed.

NP01 107 Instrumentation for Precise Energy- and Angle-Resolved Secondary Electron Emission Measurements W.Y. CHANG, *Physics Department, Utah State University, Logan, UT 84322-4415* N. NICKLES, *Physics Department, Utah State University, Logan, UT 84322-4415* R.E. DAVIES, *Physics Department, Utah State University, Logan, UT 84322-4415* J.R. DENNISON, *Physics Department, Utah State University, Logan, UT 84322-4415* The production of secondary electrons (SE) by energetic electron or ion bombardment involves multiple events including electron-electron and electron-lattice scattering. To date, the details of the mechanisms for SE production and emission are not well understood, and few accurate cross section measurements are available. Current instrumentation developed at USU has been used to measure the energy-angle resolved double differential SE cross section of elemental metals. Samples are bombarded with <20 eV to 30 keV electrons. For energy-resolved measurements, a hemispherical retarding-field analyzer is employed. A custom retarding-field Faraday cup detector, rotatable about sample position, measures the energy-angle resolved cross section. Details of instrumentation, experimental methods, and characteristic data will be presented. This work is supported by grants from the AFOSR/DURIP Program and the NASA/SEE Program.

NP01 108 Implementation of a Lock-in Amplifier with a PC VICTOR DOSSETTI-ROMERO,* *Instituto de Fisica, Universidad Autonoma de Puebla, Mexico* An inexpensive Lock-in Amplifier is designed and characterized based on the half-flash A/D converter ADC0820 and a PC. The *hardware* of the amplifier consists of a computer card with two ADC0820 ICs that sample both the modulated signal and the reference one. The modulated signal passes trough filtering and amplifying stages before entering the A/D converter. The *software* acquires the data by simulating Chevyshev and Butterworth low-pass filters that constitute the output of the Lock-in Amplifier. The results of thermal characterization of materials like Candelilla wax, titanium oxides, etc., by open cell photoacoustic spectroscopy and Newton's law of cooling techniques are compared using this amplifier and the SR510 Lock-in Amplifier from Stanford Research Systems.

*Master of Science Program student.

NP01 109 Wavelet Analysis in an Optical Computer ALBERT A. TIJERINA, DAVID L. BIXLER, ANDREW B. WALLACE, *Angelo State University.* The objective of this research is to design, construct, and test a simple optical computer, followed by an analysis of the signals generated using both Fourier Transform analysis and Integral Wavelet Transform (IWT) analysis. In order to study the spectral behavior of an analog signal from its Fourier transform, full knowledge of the signal (in the time-domain to be analyzed) must be acquired. This knowledge includes future information of the signal. In addition, if a signal is altered in the small neighborhood of some time instant, the entire spectrum is affected. Hence, in applications such as the analysis of non-stationary signals and in real-time signal processing, the use of a Fourier transform alone is inadequate. The use of IWT analysis allows room for a dilation (compression) parameter that widens (narrows) the time-frequency window according to the signal frequencies as needed. The IWT of a function simultaneously localizes the function and its Fourier transform with this zoom-in/zoom-out capability. We analyze the signals of the optical computer using both Fourier transforms and Integral Wavelet Transforms to illustrate the relative strengths and weaknesses of each method in analyzing an analog signal. This research is relevant to applications such as real-time diagnostic imaging and fiber-optic communications.

NP01 110 Combined molecular dynamics and finite element method technique as applied to laser induced pressure w ave propagation JULIA SMIRNOVA, *Penn State University* LEONID ZHIGILEI, *Penn State University* BARBARA GARRISON, *Penn State University* Analysis of a variety of dynamic phenomena requires simultaneous resolution of both atomistic and continuum length scales. A computational technique based on a combination of molecular dynamics technique and finite element method allows one to find balance between the necessary level of detail and computational cost. This technique has been implemented and tested on the propagation of a pressure wave induced by laser irradiation of organic solids. The strength of this combined approach is that a pressure wave can be transported over micron dimensions without losing the essential characteristics of the wave profile. The effect of the transition from molecular resolution in the molecular dynamics region to more coarse grid in the finite element region on the wave profile is discussed. This computational approach can be useful in cases where a detailed molecular-level analysis is necessary in localized regions which are spatially separated from each other whereas continuum mechanics and thermodynamics is sufficient in the rest of the system. In the field of laser ablation this approach can be applied to study back spallation, acoustic desorption, or laser ablation/damage of heterogeneous systems with spatially localized absorbers.

NP01 111 A Di- Central Event Plane P. VON GRONEFELD, *USNO* A certain descriptive and simple quality is derived in the spheric basis of 4-space and how it scales. It is in general terms. As volume doubles, length increases by lesser factor $\sqrt[3]{2}$, halving being inverse. Observers are at a one-way outward moving surface in respect to proper-time, origin in every direction and reference frame radio-polar. So the *complementary* proximate one-half of space is, given the outer radius as C and D observing *distance*,

$$C=\left(1-\sqrt[3]{\frac{1}{2}}\right)D.$$

A di- central event plane between halves divides space in two parts. A primary difference is it being $2/\sqrt[3]{2}$ later to one-half of linear age. The radius reflected at the observer's origin in C^3 defines a partial space in the one above, but it is unknown if it follows for there being any special importance to it.

NP01 112 An algebraic characterization of singular quasi - bi - Hamiltonian systems M.A. AGUERO, *Universidad Autonoma del Estado de Mexico, Mex.* R. ALVARADO, *Universidad Autonoma de Zacatecas, Mex.** We prove an algebraic criterion which characterize singular quasi - bi - hamiltonian structures constructed on the lines of a general, and simple, new formal

procedure proposed by the authors. This procedure shows that for the definition of a quasi-bi-hamiltonian system the requirement of non-singular Poisson tensors, contained in the original definition by Brouzet et al., is inessential. Besides, it is shown, incidentally, that one method of constructing Poisson tensors available in the literature, is a particular case of the treatment proposed in this work.

NP01 113 Nonlinear Charge Distribution and Quantum Capacitance Microscopy JIAN WANG, BAIGENG WANG, XUEAN ZHAO, *Department of Physics, The Univesity of Hong Kong, Hong Kong* HONG GUO, *Centre for the Physics of materials, Department of Physics, McGill University, Montreal, Quebec, Canada H3A 2T8* We report a general and gauge invariant theory for nonlinear DC transport in the coherent quantum regime. It is applied to investigate the nonlinear charge distribution and nonlinear electrochemical capacitance for conductors which are coupled capacitively. We derived an exact expression for the electrochemical capacitance-voltage curve in a generic form. This result suggests a *quantum scanning capacitance microscopy* at the nano-scale: by inverting the capacitance-voltage expression one is able to measure the local spectral function of a nano-system.

NP01 114 Lie symmetries of classical field theories LOUIS MARCHILDON, *Universite du Quebec* We consider systems of nonlinear partial differential equations describing classical field theories. A Lie symmetry of such a system is a transformation of the independent and dependent variables that leaves the solution set invariant and belongs to a local Lie group. The general method of finding Lie symmetries is to apply the appropriate prolongation of the symmetry generators to the equations and set the resulting expressions to zero wherever the original system of equations holds. We have applied the method to several types of equations, with or without the help of symbolic packages. In particular, we have considered the full or self-dual Yang-Mills equations, Einstein's equations in N dimensions, and the equations describing an electromagnetic field coupled to a complex scalar field or a two-dimensional spinor. Results obtained in all these cases will be reviewed and discussed.

NP01 115 Transient effects in time-dependent resonant tunneling GASTON GARCIA-CALDERON, *Instituto de Fisica, UNAM* We consider an analytic solution to the time-dependent Schroedinger equation with the initial condition of a cut off wave to investigate the time evolution of tunneling in double-barrier resonant structures. Our approach involves the S-matrix poles and resonant (Gamow) states of the problem. At resonance energy we study the buildup time of the probability density along the internal region of the structure and the formation of the propagating transmitted solution. At long times we compare the transmitted wavefront with the propagating wavefront for the free case and obtain a delay time of the same order of magnitude as obtained in the stationary-phase treatment. Ref. G. Garcia-Calderon and A. Rubio, Phys. Rev. A 55, 3361 (1997).

NP01 116 Topological and Nontopological Solitons in Ordered Systems. OLEG G. VIKHLII, *Institute of Physics, Ukrainian Academy of Sciences, Kyiv, Ukraine* SERGEI S. ROZHKOV, *Institute of Physics, Ukrainian Academy of Sciences, Kyiv, Ukraine* ROZH COLLABORATION The dynamics of the systems which are described by the order parameter taking values on the sphere is examined. There are two types of solitons (domain walls) whose existence is due to two different machanisms of the solitons size fixing (topological and nontopological). We consider a situation when topological and nontopological (higher order gradient) terms, breaking respectively the degeneracy of the equilibrium state and the scale invariance, are present in the free energy of the system. For the angle ϕ of the planar configuration of the unit-vector order parameter we find the equation of motion $\phi_{tt} = \phi^*_{xx}(1 + a\phi_x^2) + b^*\phi_{xxxx} - d^*sin(\phi)$, where x and t are nondimensional space-time variables; a, b and d are parameters of the model. This equation is novel. It has soliton solutions which combine the properties of both topological and nontopological solitons. The stability of solitons and their propagation are studied. For definite choice of parameters or space-time scales the equation goes over to the different particular equations, e.g., sine-Gordon, modified Korteweg-de Vries and other ones. We show that in the A-phase of superfluid ^{3}He the conditions for creating the nontopological spin solitons (d=0) may be realized in the presence of magnetic field. Other physical applications are discussed. We are also able to take into account in the equation the ϕ_t-type dissipative term.

NP01 117 Electron Propagator in a 3-D Saddle Point Potential in the Presence of Electric and Magnetic Fields* VASSILIOS FESSATIDIS, *Fordham University* The nonrelativistic retarded Schrödinger Green's function is derived for electron motion in a 3-D saddle point potential subject to a time dependent electric field and a constant uniform magnetic field. The saddle point potential considered here is of the form $V(\mathbf{x}_\perp, x_\parallel) = \frac{1}{2}m_\parallel\omega_\parallel^2 x_\parallel^2 - \frac{1}{2}m_\perp\omega_\perp^2 x_\perp^2$, and the electric field is oriented arbitrarily with respect to the magnetic field. Schwinger's operator of motion equation method is employed to obtain a closed form expression for the electron propagator.

NP01 118 Results of the Michelson-Morley Experiment In View of Rutherford's Discovery of the Incredible Emptiness of Atoms. MENAHEM SIMHONY, *Hebrew U.* Atomic bodies consist of nothing but nuclear praticles, very far apart from one another. In atomic bodies, distaces between the nuclei of neighboring atoms are up to 10^5 times the radii of the nuclei. If the nucleus is represented by a node of a network made of 0.1 mm thin nylon threads, then the next thread and node of the net should be a 10 m away. Such a network can move undisturbly through normal gases and liquids (even with schools of birds of herring), without making winds or currents in them (but wavelets around the nodes). Our vacuum space contains electron and positrons which, too, are far apart frome one another. The nuclear particles constituting an atomic body can move through the network of electrons and positrons in space, creating in it real EM waves of de Broglie wavelength, but no winds or currents. EM radiation, once emitted into this carrying space, propagates with a velocity c that depends on the conditions in it, not on the already forgotten velocity of the emitter. Atomic bodies, including the earth and ourselves are not dense and continuous, as perceived, and do not buldoze the electron positron network in space.[1]

NP01 119 Electronic structure of silicon based clathrate TAKATOSHI NAGANO, *School of Science and Engineering, Meiji university* HARUKI EGUCHI, *Research Institute, Ishikawajima-Harima Heavy Industries, Co. Ltd.* KAZUO TSUMURAYA, *School of Science and Engineering, Meiji university* SHIGEMITSU KIHARA, *Research Institute, Ihikawajima-Harima Heavy Industries, Co. Ltd.* D. J. SINGH, *Naval Research Laboratory* Recently, silicon based clathrates draw much attention with discovery of superconductivity in the silicon based clathrate that is Si_{20} based materials alkali (Na) and Alkaline-earth (Ba) atoms locate in the silicon cluster cage. For further finding of new superconductors and additional characters, it is essential to study bonding character of this materials. The first principle norm-conserving pseudopotential with a planewave basis set and super-cell approximation employ the silicon based clathrate that an aluminum atom locates in the silicon cluster cage. We calculate the second derivatives of charge density with respect to position to clarify covalent bonding strength among atoms in the clathrates. We discuss the bonding character differences between silicon - silicon and silicon - aluminum.

NP01 120 Special Points for (GaAs)/(Ge_2) Semiconductor Superlattices J. RUFINUS, *University of Wisconsin-Madison and University of Wisconsin-Whitewater* G. E. CROOK, *University of Wisconsin-Madison* The special point method has been used for many years to do electronic structure calculation of solids. Here we obtain and discuss the special points for performing integrals over the Brillouin Zone of (GaAs)/(Ge_2) Superlattices. If the period of the Superlattice is taken properly the number of special points can be greatly reduced, thus making the calculations much faster.

NP01 121 Meter-Scale Model of a Scanning Force Microscopy Cantilever Operating at High Frequencies JUAN C MERCED, FREDY R ZYPMAN, *University of Puerto Rico - Humacao* Scanning Force Microscopes (SFM) provide microscopic information of surface morphology. At each point on the surface, it is also possible to measure a force-separation curve, which provides chemical information of the region. In order to obtain that kind of curve, the sample is approached towards the tip and the tip deflection, due to changing tip-sample forces, is recorded. Then, for each separation, the tip deflection is multiplied by the cantilever's spring constant to obtain the desired force. Lately, the SFM community has recognized the importance of allowing the cantilever to move fast in order to make movies of biomolecules. Fast motion implies excitation of higher vibrational modes in the cantilever. Thus, the force is no more obtained via Hooke's law. We present results on how to properly analyze the high frequency data to extract the force. In addition, we have built a large-scale model of the cantilever for educational purposes. This project is supported by NSF grant number DMR-9872689

NP01 122 A scheme to improve the quality of pseudopotential and to reconstruct all-electron wave functions CHUN QIAN, *Phys. Dept., Florida International Univ.* XUEWEN WANG, *Phys. Dept., Florida International Univ.* The norm-conserving pseudopotential method has been used in calculations of electronic structures of a wide range of materials and systems. We propose a method to improve the quality of the pseudopotential by improving the matching of higher orders of energy derivative of wave functions' logarithmic derivative at the cut-off radius. By direct modification to the pseudopotential is applied to minimize the error of logarithmic derivative over a certain energy range. We were able to improve the quality of the standard norm-conserving pseudopotential. The energy derivative are calculated from differential equations derived directly from Schrödinger's equation. For heavy atoms, the energy derivative for all-electron wave functions are calculated using spin-averaged Dirac equation. Results for simple atoms as well as heavy atoms will be presented. The same approach also give us the suitable localized functions to reconstruct the all-electron valence wave functions. Use the core-orthogonalization scheme, the all-electron wave functions of Li and Si were reconstructed from the pseudo wave functions.

NP01 123 Accurate and Efficient Perturbation Theory by Matrix Inversion CAMERON REED, *Alma College* An approach to time-independent perturbation theory is developed which has significant advantages over the traditional Rayleigh-Schroedinger method. With this new approach, energies and wavefunctions corresponding to perturbations of arbitrary strength acting on either degenerate or non-degenerate systems can be efficinetly recovered via a conceptually straightforward matrix-inversion scheme. Tedious summations are eliminated, and no integrals beyond those appearing in first-order perturbation theory need be computed.

NP01 124 Electronic band structure of $CaCuO_2$ and $SrCuO_2$ H. WU, Q.Q. ZHENG, *Institute of Solid State Physics, Academia Sinica, 230031-Hefei, China* The discovery of high-temperature oxide superconductors stimulates much interest in low-dimensional spin systems. By means of band calculations within both the local-spin-density approximation (LSDA) and the on-site Coulomb correlation U correction (LSDA+U), we have investigated the electronic structure of the Cu^{2+} spin=1/2 antiferromagnetic insulators, the two-dimensional (2D) $CaCuO_2$ and the 1D $SrCuO_2$. The LSDA calculations show that strongly orbital-dependent exchange splittings open an insulating gap in $SrCuO_2$, which is in contrast to the metallic solution for $CaCuO_2$ due to the enhanced p-d hybridization in the 2D CuO_2 plane. While the U correction to the local Cu 3d orbitals in both the cuprates leads to an insulating state in agreement with the experimental results.

NP01 125 Selective Resonant Tunneling and Damp-Matching XING ZHONG LI, *Dept. of Physics, Tsinghua University** The resonant quantum tunneling current through the barrier between two wells may be maximized when the damp (absorption) in one well matches the barrier parameters. The maximum resonant tunneling current is much greater than the conventional expectation by a large factor of $\theta(\theta^{-2}$ is the conventional barrier tunneling factor). Thus, the resonant tunneling would select not only the right energy level, but also the right damping. In other word, when the barrier is thick and high the damp-matching would select only the energy level which has a long life-time. The implication of this resonant tunneling model would be discussed in quantum spin tunneling and nuclear physics

NP01 126 Self-Consistent Calculation for the Interface Between the Semiconductor and Vacuum CHIN-SHENG WU, *Division of General Study, Yuan-Ze University, Taiwan* We apply the density-functional theory to calculate the junction characteristics between the semiconductor and vacuum. We obtain the self-consistent solution of the charge distribution around the interface. The zero-temperature form of the exchange-correlation potential

which corrected by Sham for semiconductor is used, but full account is taken through the Fermi distribution function of the finite-temperature occupancy effects. We also apply the effective mass approximation to the Schroedinger equation in our method. The electronic structure and potential for the interface are reported. Our calculations for the semiconductor with the conduction electron densities r=24, 36, and 48 a.u.

NP01 127 Tight-Binding in Diamond Structure Materials: Bulk Phases and Phonons Common HPC Software Support Initiative (CHSSI)* M. J. MEHL, D. A. PAPACONSTANTOPOULOS, N. BERNSTEIN,† *Complex Systems Theory Branch, Naval Research Laboratory, Washington DC* F. KIRCHHOFF, F. S. KHAN, *Department of Electrical Engineering, Ohio State University, Columbus, OH* The NRL-developedtight-binding method[1] has recently been extended to Carbon (in both sp^2 and sp^3-bonded phases) using only s and p orbitals, and to Si, using s, p, and d orbitals.[2] We have now improved the parametrization of Si by fitting to the experimental electronic band gap, and developed parameters for Germanium, also fitted to the observed band gap. Here we look at the relative stability of the bulk structures of all three elements. Using the tight-binding formalism and theDoD-TBMD program, we can directly determine the dynamical matrix of the diamond structure of each element. From this we determine the phonon spectra. If time permits, we will also determine the thermal expansion parameter for all three elements.

NP01 128 ^{7}Li nuclear magnetic resonance relaxation measurements on LiMPSA + [2.2.2] Cryptand E. E. SIGMUND, *Northwestern University* W. P. HALPERIN, R. E. A. DILLON, D. F. SHRIVER, Z. N. DING, D. E. ELLIS, *Northwestern University* ^{7}Li nuclear spin-lattice relaxation and spin-spin relaxation measurements have been performed on the amorphous electrolyte system consisting of Lithium N-(3-methoxypropyl)trifluoromethanesulfonamide salt added to a [2.2.2] cryptand. The cryptand's enhancement of the cationic mobility and thus the ionic conductivity is discussed. The relaxation data fits well to a single correlation time model for the spectral density of the lithium ionic motion. A single activation energy and attempt frequency have been measured for the lithium ion motion using the spin-lattice relaxation data. Comparison of these measurements to motion parameters extracted from an electronic structure calculation of the cryptate's electrostatic potential is discussed. This work is supported by the NSF-MRSEC program through the Materials Research Center at Northwestern University, grant DMR-9357506.

NP01 129 Finite Size Scaling method for the Stability of Atomic and Molecular Ion SABRE KAIS, *Purdue University, Department of Chemistry, U.S* PABLO SERRA, *Universidad Nacional de Cordoba, Argentina* Phase transitions at absolute zero temperature can take place as some parameter in the Hamiltonian of the system is varied. For such transitions, crossing the phase boundary means that the quantum ground state changes in some fundamental way. For the Hamiltonian of N-electron atoms, this parameter is taken to be the nuclear charge. As the nuclear charge reaches a critical point, the quantum ground state changes its characters from being bound to being degenerate or absorbed by a continuum. We describe finite Size Scaling method to calculate the critical nuclear charge for which an atom can bind an extra electron to form a stable negative ion. The method can be generalized to calculate other critical phenomena in atomic and molecuar system.

NP01 130 Stability of one-electron bond in a strong magnetic field QICUN SHI, *Department of Chemistry, Purdue University, West Lafayette, IN 47907* JACK YANG, *Department of Chemistry and Department of Physics, Purdue University, West Lafayette, IN 47907* SABRE KAIS, *Department of Chemistry, Purdue University, West Lafayette, IN 47907* Stability in a system $Z_AZ_Be^-$ consisting of two nuclear centers with charges Z_A, Z_B and one electron is studied as a function of $q = Z_A/Z_B$ and magnetic field B. Our results are based on fully numerical approach and variational calculations. Critical charge parameters separating the regime of stable and unstable binding energies are calculated as a function of the magnetic field. Results show that the stable binding region $0 < Z_A \leq 1.236$ in the free field becomes smaller as B increases. For $q=1$, the critical magnetic field $B_c=0.94$ a.u. corresponds to a critical charge $Z_c=0.86$ where the molecular binding energy equals to zero. Stability is also studied for different values of the parameter q. The stability scenario of states in a strong megnatic field are not restricted to one-electron systems, but can be expected also to be of relevance for more general situations of atoms and molecules.

NP01 131 Exact Exchange-Correlation Energy Functional for a System of Spinless Fermions H. L. NEAL, *Physics Dept. and CTSPS, Clark Atlanta U., Atlanta, GA 30314* We obtain an explicit exact expression for the exchange-correlation energy functional $E_{xc}[\rho]$ for systems of harmonically interacting spinless fermions. The construction of $E_{xc}[\rho]$ is made possible by a mapping procedure that exploits its universal property. We denonstrate the procedure and discuss its implications for the Coulomb interaction.

NP01 132 A time-dependent quantum mechanical model of photoexcitation in conjugated polymers MARK N. KOBRAK, *Department of Chemistry, University of Houston* ERIC R. BITTNER, *Department of Chemistry, University of Houston* We treat photoexcitation in conjugated polymers as the creation of a particle-hole pair, and model these quasiparticles using a formally exact time-dependent wavepacket treatment. The polymer lattice is treated as a set of classical oscillators interacting with the quantum particles. The model, which permits exciton- and polaron-like states, allows us to examine the role of the lattice with respect to ultrafast spectroscopic observables such as the time-dependent Stokes shift (exciton-polaron formation energy) and the nature of vibrational coupling between the dipole-allowed 1Bu singlet state and the lowest lying triplet excited electronic state.

NP01 133 A generalized Lagrangian approach for excited state molecular dynamics in the random phase approximation. ERIC R BITTNER, *Department of Chemistry, University of Houston* DANIL S. KOSOV, *Department of Chemistry, University of Houston* This paper reviews our efforts towards developing methods to do molecular dynamics in electronically excited systems using a first principles description of the forces. Our method is based upon a Lagrangian treatment of the electronic excited state energy functional which depends parametrically upon the classical positions of the nuclei. Working within the random phase approximation, we derive coupled equations of motion for the electronic amplitudes (for both the ground and excited state orbitals) and the nuclear coordinates. Model calculations on linear polyenes will be presented and we discuss the advantages and disadvantages of our methods.

NP01 134 Lennard-Jones as a Model for Argon and Test of Extended RG Calculations J. A. WHITE, *American University* Pressure isotherms for argon measured at temperatures somewhat below and above the critical point, for densities from 5% to somewhat more than twice that at the critical point[1], together with a model Lennard-Jones intermolecular potential, have been used to test features of an extended renormalization group (ERG) theory for fluids.[2] In particular, in addition to choices for the Lennard-Jones model parameters sigma and epsilon, theoretical ERG predictions of nonuniversal thermal quantities depend also on the choice made for the ratio of edge of averaging volume to current fluctuation wavelength in the renormalization procedure and in addition somewhat upon the precise value chosen for smallest fluctuation wavelength considered (generally taken to be between about three and five times the "sigma" of the model). Results will be discussed in relation to the question "To what extent could the ERG procedure have been relied upon to make a priori predictions for argon?"

NP01 135 Spatial de-orientation lifetimes for upper Stark state selected beams of CH_3F, CH_3Cl, CH_3Br and CH_3I in field-free space. PETER W. HARLAND, *Chemistry Department, University of Canterbury, Christchurch, New Zealand* WAN-PING HU, CLAIRE VALLANCE, *Chemistry Department, University of Canterbury, Christchurch, New Zealand* PHILIP R. BROOKS, *Chemistry Department, Rice University, Houston, Texas* The mean lifetimes for spatial scrambling or deorientation of upper Stark state ($KM_J < 0$) selected beams of CH_3F, CH_3Cl, CH_3Br and CH_3I in field free conditions have been measured. Supersonic beams were quantum state selected in a hexapole inhomogeneous electric field and directed through a uniform electric field maintained between a pair of parallel field plates before focusing through a second hexapole field to a quadrupole mass spectrometer detector. Orientation effects were measured *via* the effect of the uniform field on the beam signal. The beam signal at the detector was shown to remain constant for uniform field strengths greater than approximately 3 Vcm^{-1}. A drop in signal of around 40% was observed when the field strength was switched from > 3 Vcm^{-1} to zero field due to spatial scrambling of the molecular dipoles and subsequent loss of lower Stark states ($KM_J < 0$) and partial loss of $KM_J = 0$ states, which previously would have remained in upper Stark states, in the B field. Mean scrambling lifetimes were measured by subjecting the molecular beam to field free conditions for increasing time periods and measuring the effect on the beam attenuation. The mean deorientation lifetimes for CH_3F, CH_3Cl, CH_3Br and CH_3I were found to be 277, 257, 241 and 238 μs respectively. These lifetimes are consistent with the observation of asymmetry effects previously reported for collisions of electrons with oriented molecules in experiments where the orienting field was switched to zero prior to electron impact ionization[1].

[1]Aitken *et al*, J. Chem. Phys., 1994, 101, 11074 Aitken *et al*, Int. J. Mass Spectrom. Ion Processes, 1995, 149/150, 297

NP01 136 Studies of electron - molecule collisions using crossed beams and ion imaging. PETER W. HARLAND, CLAIRE VALLANCE, *Chemistry Department, University of Canterbury, Christchurch, New Zealand* A crossed molecular beam machine has been constructed to investigate collisions between electrons and spatially oriented symmetric top molecules. Supersonic beams of neat and seeded symmetric top molecules, such as CH_3F, are quantum state selected and spatially oriented using a combination of inhomogeneous and homogeneous electric fields. The molecular beam is crossed with an energy selected pulsed electron beam and the products of ionization detected using an ion imaging system. This allows product angular differential cross sections and velocity distributions to be determined.

NP01 137 Molecular Dynamics Simulations of Drift Tubes Experiments ROMAN BARANOWSKI, *UBC* MARK THACHUK, *UBC* The transport properties of ions drifting through neutral atomic gases under the influence of the uniform electrostatic field are studied by molecular dynamics simulations. For representative system, NO^+ in He, the drift velocities, effective temperatures and ionic diffusion coefficients in the direction parallel and perpendicular to the applied field have been obtained, and the comparison with the experimental and theoretical results on the same system have been performed. The good agreement between the results establishes the validity and accuracy of the method and enables us to pursue the analysis. In particular the velocity and angular momentum correlations functions, translational and rotational energy distributions, orientation and alignment parameters have been obtained for NO^+ and other model systems in order to probe the sensitivity of these properties on different geometries, interaction potentials and charge distributions. Furthermore the assumption that the different isomeric structures can be distinguished on the ground of their mobility alone have been investigated.

NP01 138 Ab initio studies of the Na^+-N_2 and Na^+-O_2 ion–molecule complexes. BENJAMIN C. SHEPLER, ROBERT J. HINDE, *Department of Chemistry, University of Tennessee, Knoxville, TN 37996* Long-lived Na^+-N_2 ion–molecule complexes have been implicated in the chemistry of meteoritic sodium in Earth's upper atmosphere. Accurate estimates of the lifetime of these complexes require knowledge of the Na^+-N_2 potential surface. We present a global (rigid rotor) ab initio potential surface for Na^+-N_2, computed at the MP4 level using large correlation-consistent basis sets. We compare the long-range behavior of this ab initio surface with that of a model surface based on electrostatic and induction contributions. We also compare the Na^+-N_2 and Na^+-O_2 interactions. The Na^+-N_2 complex is more strongly bound than the Na^+-O_2 complex, and has a much more anisotropic potential surface.

NP01 139 Rotational excitation of CH^+ in collisions with He. ROBERT J. HINDE, *Department of Chemistry, University of Tennessee, Knoxville, TN 37996* Far-infrared emissions attributed to pure rotational ($j \rightarrow j - 1$) transitions of CH^+ have recently been detected from the direction of planetary nebula NGC 7027.

The CH^+ ions are rotationally hot, with significant population in rotational levels up to $j = 6$. Collisions between CH^+ and H, H_2, or He could populate these rotational levels. We present a CCSD(T) ab initio potential surface for He + CH^+ collisions and use this surface to compute rate constants for the production of rotationally excited CH^+.

NP01 140 Peculiar non-adiabatic effects in the photoelectron spectrum of allene (1,2-propadiene) A.D.O. BAWAGAN, *Department of Chemistry, Carleton University, Ottawa ON K1S 5B6 Canada* J. BOZEK, *Advanced Light Source, Berkeley CA 94720 USA* E. KUKK, *Advanced Light Source, Berkeley CA 94720 USA* E.R. DAVIDSON, *Department of Chemistry, Indiana University, Bloomington IN 47405 USA* The synchrotron photoelectron spectra (PES) of allene (C3H4) at 20-120eV photon energies have been obtained at the ALS beamline 10.0.1. The study reveals, for the first time, additional structure around the 12.7eV binding energy peak which has been observed previously [Chem Phys Lett 287,61(1998)]. The additional structure confirms the previous theoretical interpretation that the very low intensity PES peaks around 12.7eV result from peculiar non-adiabatic effects or strong vibronic coupling (Jahn-Teller-like) between at least two electronic states — one of which is a correlation state.

NP01 141 Experimental Studies of the simplest fluxional anion, methide, CH_3-* STEPHEN MITCHELL, *Department of Physics, University of Nevada, Las Vegas* JOHN FARLEY, *Department of Physics, University of Nevada, Las Vegas* Anions exhibit an enhanced sensitivity to electron correlation effects, and thus are good systems for studying electron correlation. CH3- does not have a fixed structure but instead exhibits an inversion motion, similar to the motion in the isoelectronic neutral NH3. The inversion frequency in CH3- is expected to be very sensitive to the details of the potential, including electron correlation effects. Theoretical calculations variously predict that electron correlation will either increase[2] or decrease[3] the tunnelling rate, depending on the theoretical approach. Methide has a small (0.08 eV) electron affinity and vibrationally excited states are expected to autodetach. Methide is thus a good candidate for autodetachment spectroscopy. There is little experimental data on this simple system and none at high resolution. Production of adequate beams of CH3- is experimentally challenging. Progress will be reported in our studies of methide. [2]. D. S. Marynick and D. A. Dixon, Proc. Natl. Acad. Sci U. S. A. 74, 410-413 (1977). [3]. F. Driessler et al., Theo. Chim. Acta (Berlin) 30, 315-326 (1973); C. E. Dykstra et al., J. Chem. Phys. 67, 4071 (1977).

*Supported by DOE EPSCoR

NP01 142 A Scaling Method for Computing Scattering Between Atomic Helium Beams H. H. HJORT, D. O. EDWARDS, S. A. VIZNYUK, *Physics Department, The Ohio State University* We describe a scaling method for calculating the scattering between and within beams of helium atoms. The number of atoms N in the beams is reduced by a large scaling factor λ while the collision cross-section is increased by λ. This leaves the rate of scattering for each particle unchanged. As an example of the method, we predict the outcome of a low temperature atomic beam experiment designed to measure the ^4He–^4He atomic scattering cross-section σ at low energies. Because of the existence of a very weakly bound dimer, the low energy cross-section is expected to be unusually large, $\sim 1.83 \times 10^5$ Å ^{2}. In the simulation N/λ is small enough for the trajectories of all the scaled atoms to be calculated numerically. The simulation shows that the experiment is quite practicable. The proposed apparatus is just over 20 cm long, and a few centimeters wide, small enough to fit in a dilution refrigerator. The heaters and bolometers are assumed to be similar to those used in previous low temperature scattering experiments. We show that, using low intensity beams, the cross-section can be measured as a function of the relative velocity v_r. By fitting $\sigma(v_r)$ one can determine the scattering length and effective range of the interaction. We also predict that, at high intensity, the two beams coalesce into a single beam.

NP01 143 Molecular Detachment Spectroscopy of Triplet He_2^* on Helium Nanodroplet Surfaces C.-C. HU, R. PETLURI, J. A. NORTHBY, *Physics Department, University of Rhode Island* Metastable excitations produced in a beam of helium nanodroplets by electron bombardment evolve into triplet He_2^* molecules bound on the droplet's surface. Absorption of an infrared photon can lead to the detachment of a molecule. When a detached metastable molecule hits the walls surrounding the beam it releases an electron which can be counted. We will describe the spectral dependence of this effect in the region of the $c^3\Sigma_g^+ \leftarrow a^3\Sigma_u^+$ transition of the free molecule. We observe very sharp but highly structured spectral lines, which carry detailed information about the molecule and its unusual rotational distribution, about its interaction with the helium surface, and about the dynamics of the underlying droplet.

DHPP: DIVISION OF HIGH POLYMER PHYSICS (PART II)

NP01 144 Mechanical Properties of Poly(ethylene oxide)/Poly(L-lactide)/Compatibilizer Ternary Blend IN-JOO CHIN, KWANG-SOK KIM, DONG-HUN KEE, JIN-SAN YOON, *Dept. of Polymer Sci. and Eng., Inha Univ., Inchon 402-751, Korea* JIN-SU JUNG, *Small and Medium Industry Promotion Corp., Ansan 425-130, Korea* Diblock and triblock copolymers of poly(ethylene glycol)(PEG) and poly(L-lactide)(PLLA) were used as the compatibilizer for the biodegradable PEO/PLLA (60/40) blend. Poly(vinyl acetate)(PVAc) was used as another compatibilizer for the same blend. Overall mechanical properties of the PEO/PLLA blends were enhanced only marginally, when diblock and triblock PEG-PLLA copolymers were utilized, because the molecular weights of the PEG-PLLA block copolymers were shorter than that of individual homopolymers comprising the blend. When PVAc was added to the PEO/PLLA blend, the spherulitic growth rate of PLLA in the blend decreased and the characteristic crystalline features of the PLLA spherulite became less obvious. Tensile properties were affected greatly by the method of blend preparation and the annealing time. As long as the effect of quenching was suppressed, PVAc was found to be entrapped inside the PLLA spherulites, resulting in an increase in the toughness of the crystalline PEO/PLLA blend.

NP01 145 Observation of Boson Peaks by Inelastic Neutron Scattering In Polyolefins* B. K. ANNIS, *Oak Ridge National Laboratory* D. J. LOHSE, *Exxon Research & Engineering Co.* F. TROUW, *Argonne National Laboratory* Inelastic neutron scattering was used to probe the nature of the boson peak in atactic poly-propylene (aPP), head-to-head polypropylene (hhPP), polyisobutylene (PIB) and a 1/1 volume ratio hhPP/PIB blend. Atactic

polypropylene is among the most "fragile" of glass formers and was found to have a shoulder rather than the distinctive peak exhibited by hhPP at an equivalent displacement from the glass transition. This appears to be due to both an increased density of states for aPP at the the lowest temperature measured (15 K) and the more rapid development with temperature of a fast process. The difference in the boson peak behavior suggests that the fragilities of hhPP and aPP are quite different. For the three pure, chemically similar polymers the position of the boson peak can be correlated with the glass transition temperature, the cohesive energy density and the characteristic ratio. In general this is not the case for chemically dissimilar molecules. PIB is miscible with hhPP but not aPP and the dynamics generating the boson peak in the blend appear to be intermediate between those of the pure components.

NP01 146 Designing High-performance Fibers with Improved Compressive Strength SHAWN JENKINS, *Georgia Tech* KARL JACOB, SATISH KUMAR, *Georgia Tech* THUY DANG, *University of Dayton Research Institute* FRED ARNOLD, *WL/MLBP, Wright Patterson Air Force Base, Dayton, OH* Significant progress has been reported in improving the compressive strength of high performance polymeric fibers via the introduction of crosslinks or bi-directional hydrogen bonding. In order to quantify the effect of the latter on the compression behavior of rigid-rod polymers, we are investigating systems (i) void of hydrogen bonding, (ii) with one-dimensional hydrogen bonding, and (iii) with two- dimensional hydrogen bonding. Moreover, ab initio calculations are being employed to study the affect of intra vs. intermolecular hydrogen bond formation on compressive strength. In a previous study on the effects of crosslinking, an anisotropic residual stress was found to form on crosslinking in MePBZT fiber. We are currently pursuing approaches to measure and, if possible, eliminate the development of stresses on crosslinking. Results of these studies will be presented.

NP01 147 Physical Aging Behavior of Substituted Poly(p-Phenylenes) DERRICK DEAN, *BFGoodrich Company* RICHARD VAIA, *Materials Directorate, Air Force Research Laboratory* MARK TRIMMER, *Maxdem, Inc.* The effect of varying the molecular structure on the physical aging behavior of poly(p-phenylenes) substituted with benzoyl and 4-phenoxybenzoyl groups and a copolymer of benzoyl-1,4-phenylene and 1,3-phenylene has been investigated by studying their volumetric and enthalpic relaxation behavior. The 4-phenoxybenzoyl substituted polymer was shown to have the largest volumetric relaxation rate. Master curves from the the volumetric and the enthalpic relaxation data have been prepared. The shift factors obtained can be fit to the WLF equation, and agree well with shift factors previously obtained from master curves generated by dynamic mechanical data. The times to reach equilibrium as well as the relative approach to equilibrium as measured by the two methods will be discussed for the three polymers, and in turn compared to that obtained for other polymers.

NP01 148 Droplet size hysteresis and coalescence kinetics in immiscible polymer blends A. J. RAMIC, *Case Western Reserve U.* S. D. HUDSON, *Case Western Reserve U.* A. M. JAMIESON, *Case Western Reserve U.* I. MANAS-ZLOCZOWER, *Case Western Reserve U.* Shear-induced droplet breakup and coalescence in binary polymer blends was investigated by optical microscopy during simple shearing. The steady-state droplet size was investigated as a function of shear rate, and the kinetics of droplet-size evolution was monitored after either a step up or step down in shear rate, which produced droplet breakup or coalescence, respectively. In each of four blend systems, the steady state size produced by coalescence was equal to that produced by breakup. Therefore, no permanent hysteresis was observed. However, a significant temporary hysteresis occurs, because of the relatively slow kinetics of coalescence. The amount of strain required to achieve steady state was investigated as a function of the composition of the system and of the shear-rate step-down ratio. Coalescence requires two events: droplet collision and drainage of the matrix fluid film between them. For gentle collisions, i.e. large step-down ratio, the probability of film drainage is unity and the kinetics of droplet collision can be measured independently. The authors gratefully acknowledge the financial support of the Goodyear Tire and Rubber Co., GE plastics, and NSF grant #CTS-9731502.

NP01 149 The Relevance of Modeling Amorphous State Waxd Scattering to the Phase Morphology and Melting in Branched, Metallocene Polyethylenes M-H. KIM, KENNETH MONAR, ANTON HABENSCHUSS, *Oak Ridge National Laboratory* Waxd and DSC analyses were performed on a wide range of branched polyethylenes. Waxd liquid scattering in the melt in the region of the low angle amorphous halo revealed a temperature dependent fraction and a temperature independent fraction. The liquid state is modeled in such a way to semi-quantitatively represent inter- and intra-molecular scattering, based on literature references in studies designed to resolve this dependency. Properly defined, the liquid fraction is shown to be 5-8% empirical fitting and, for the first time, permits the interfacial content to be revealed by Waxd for polyethylenes. When combined with temperature resolved Waxd lattice studies and DSC, the phase analysis permit a quantitative description of the real melting points. A large portion of the melting endotherm, in highly branched systems, is associated with annealing and cannot be fully correlated with the crystals. As such, it is suggested to result from a large 'tethered' liquid like fraction.

NP01 150 Electrospinning of polyethylene oxide solution SUREEPORN KOOMBHONGSE, DARRELL H. RENEKER, *Department of Polymer Science, The University of Akron, Akron, Ohio 44325-3909* In the electrospinning process, electrostatic force is used to spin ultra thin fibers. Parameters that control this process include the volume flow rate of the solution, applied voltage, jet current, jet diameter, jet velocity, concentration of the solution and the electrical field. The jet was projected upwards from a droplet sitting on the top of a 3 mm diameter glass tube. The feed rate of poly(ethylene oxide) solution into the droplet was set at particular values and the electric field was adjusted to give a quasi-stable jet, that is a jet which carried solution away from the droplet at the feed rate. When the feed rate did not equal the flow rate of the jet out of the droplet, the shape and the volume of the droplet changed and the jet became unstable. Jet oscillation, jet vibration and the formation of multiple jets were observed and recorded with a video camera. At high feed rates and high applied voltages, a single jet is very unstable and multiple jets are formed. The relationship between jet current and electric field intensity was measured. Increasing the electric field increased both jet diameter and jet velocity and hence the volume flow rate of the jet. Data on the shape of the jet are compared to theoretical predictions.

NP01 151 Secondary Crystal Melting in Ethylene-Methacrylic Acid Ionomers Y.-L. LOO, R. A. REGISTER, *Princeton University* B. S. HSIAO, *SUNY - Stony Brook* The detailed structure of ethylene-methacrylic acid (*E/MAA*) ionomers, which contain both polyethylene (*PE*) crystallites and ionic aggregates, remains a sub-

ject of debate. DSC heating thermograms of annealed or slow-cooled *E/MAA* ionomers typically show two endotherms. The higher-temperature endotherm ($\sim 90^{o}$C) is universally attributed to the melting of primary *PE* crystallites. The origin of the lower-temperature endotherm ($\sim 50^{o}$C) is less clear; it has been suggested that this endotherm arises from an order-disorder transition within the ionic aggregates. We have studied the structural changes occurring on heating in several *E/MAA* ionomers by simultaneous SAXS/WAXS/DSC. The *PE* (110) reflection in the WAXS data decreases modestly but monotonically on heating through the low-T endotherm. More significantly, the intensity of the principal SAXS peak ($q \approx 0.5nm^{-1}$) increases significantly on heating through the low-T endotherm, then decreases as the primary *PE* crystals melt at the high-T endotherm. We thus attribute the observed low-T endotherm to the melting of very small secondary crystals which form between the primary *PE* crystallites on annealing or slow cooling. When these secondary crystals melt, the electron density difference between the primary *PE* crystallites and the interlamellar regions (which contain the ionic aggregates) increases, increasing the intensity of the SAXS peak.

NP01 152 Solid-State Complexes of Branched Poly(ethyleneimine) and Dodecyl Benzene Sulfonic Acid: Self-Assembled Structure and Thermal Properties* HSIN-LUNG CHEN, *Dept. of Chemical Eng.,National Tsing Hua Univ.,Taiwan* MING-SIAO HSIAO, *Dept. of Chemical Eng., National Tsing Hua Univ., Taiwan* Supramolecular structure and thermal properties of the solid-state complexes of a highly branched poly(ethyleneimine)(PEI) and dedecyl benzene sulfonic acid(DBSA) surfactant (surf) have been investigated. Polarized optical microscopy and small-angle X-ray scattering (SAXS) revealed the presences of mesomorphic phases and microphase-separated lamellar morphology consisting of alternating polymer and surf layers. The ordered supramolecular structure was observed over a wide composition range. Consequently, the high branching level of PEI chains did not undermine the ordered packing of alkyl tails in the complexes. The thicknesses of polymer and surf layers were determined from the one-dimensional correlation function. The glass transition temperature of PEI was raised by complexation. Complexation with DBSA also enhanced the thermal stability of PEI, where the thermal decomposition temperature can be raised by as many as 50 C.

NP01 153 Effects of Pendent Chain and Backbone Lengths on the High Temperature Dielectric Spectra of Tyrosine-Derived Biopolymers NERY SUREZ, *Universidad Simn Bolvar* STEPHEN BROCCHINI, *University of London* JOACHIM KOHN, *University of Rutgers* In this work we present a comparative study of the high temperature dielectric spectra in a series of four tyrosine-derived polycarbonates and four tyrosine-derived polyarylates. The pendent chain of the polycarbonates was varied in steps of two methylene groups from two to eight carbons. The number of methylene groups of the polyarylates backbone was increased in steps of two from two to eight carbons. The Thermally Stimulated Depolarization Current (TSDC) technique was used to obtain the high temperature dielectric spectra. Each spectrum shows a very intense and sharp current peak, A peak, indicative of the glass transition relaxation of the polymer. The analysis and comparison of the observed relaxations provided correlations with pendent chain and backbone lengths. A linear relationship was obtained between the temperature of the current maxima of the A peak and the number of methylene groups. The results found suggested that the effect of methylene groups on polymer mobility and packing efficiency was independent of the position of the methylene groups within the polymer molecule. Concerning the polarization built up for the A peak, six methylene groups were found to be the threshold for an introduction of an extra effect in polymer structure.

NP01 154 Ellipsometric Determination of the Glass Transition in Thin Polymer Films MICHAEL BANACH, *University of Cincinnati, Department of Materials Science and Engineering* STEVE CLARSON, *University of Cincinnati, Department of Materials Science and Engineering* GREG BEAUCAGE, *University of Cincinnati, Department of Materials Science and Engineering* RICH VAIA, *Air Force Research Laboratory, AFRL/MLBP, 2941 P St, WPAFB, OH* A spectroscopic ellispometer equipped with a hot stage was used to investigate thermal transitions of thin (.1-1 micron) and ultrathin (less then100 nm) polymer films. The glass transition was determined by identifying inflection points in the temperature dependent behavior of the ellispometeric parameters (Δ and Ψ). This work parallels prior efforts by Keddie (1994) where he used an ellispometric technique to show substrate and thickness dependencies for the glass transition temperature in polymer films. The present study focuses on understanding the thermal transitions observed in both Δ and Ψ as a function of the heating and cooling rate. The possibility of dewetting was investigated at elevated temperatures. Understanding the ellipsometric technique for random coil polymers has produced a sensitive tool for studying films for specialized applications such as concentrated polymer solutions of optically active dyes. Keddie, et al (1994) Europhys. Lett., 1, 59. Beaucage, et al (1993) J. Polymer Science: B Polymer Physics, 31,319.

NP01 155 Controlled Dewetting in Confined Geometries via Photo Patterned Ultra Thin Capping Layers H. GRÜLL, A.R. ESKER, C.C. HAN, *NIST, Polymer Division* G. WEGNER, *Max-Planck Insitut für Polymerforschung, Mainz, Germany* Polystyrene dewetting represents an area of intense scientific interest. Optical and atomic force microscopy provide convenient ways to characterize this process. In this study, thin films of polystyrene are spin-coated on rigorously cleaned hydrophilic silicon wafers. These wafers are then covered with ultra-thin capping layers of isopentylcellulose cinnamate by the Langmuir-Blodgett technique. The thickness of the photo cross-linkable capping layers can be controlled in increments of 10 Å. In the non cross-linked regions, dewetting is initiated upon annealing. Cross-linking the capping layer has profound effects on the rate of dewetting. This difference has been exploited to photo pattern the surface. Non cross-linked regions undergo rapid dewetting which effectively confines the regions underneath the cross-linked capping layer. This leads to a wide variety of dewetting patterns that depend on both the size and shape of the cross-linked region.

NP01 156 Adhesion to Rough Surfaces HO-CHEOL KIM, LEE ROCKFORD, THOMAS P. RUSSELL, *Polymer Science and Engineering Department, University of Massachusetts, Amherst* The effect of surface roughness on adhesion has been examined by the JKR method. Artificially roughened substrate surfaces were prepared by thermal evaporation of pure calcium fluoride (CaF_2) onto silicone wafers. Root-mean-square roughness of the substrates was found to vary from 25Å to 125Å with the CaF_2 thickness. Hemispherical lenses of cross-linked hydroxyl-terminated poly(dimethylsiloxane) (PDMS) were subject to loading and unloading on the substrates. The adhesion values obtained by fitting the JKR model to loading data were decreased with increasing roughness of the substrates and only 45Å rms roughness is sufficient to reduce the adhesion to a very small fraction of its value for smooth surface.

NP01 157 Determination Of Three Dimensional Refractive Indices And Absorption Coefficients For Anisotropic Polymer Films By Prism Waveguide Coupling TAO LIU, *School of Textiles & Fiber Engineering* ROBERT SAMUELS, *School of Chemical Engineering, Georgia Institute of Technology* A Metricon PC-2010 prism waveguide coupler has been used to obtain the three dimensional refractive indices of oriented free standing polymer films (1) (2), but the mode equations used neglect the effects of air gaps and polymer film absorption. General mode equations are developed here, which consider the effects of air gap between both the prism and the polymer film as well as absorption of the polymer film. Levenberg-Marquardt algorithms implemented by Optimization TOOLBOX for MATLAB was used to extract the three- dimensional refractive indices, three dimensional absorption coefficients, and the thickness of polymer film by fitting the effective refractive indices of modes measured by the Metricon PC-2010. As an example, two polymer films, spin coated PPV (polyphenylenevinylene) and cast PMDA-ODA polyimide, are analyzed. The three-dimensional refractive indices, three dimensional absorption coefficients and the film thickness are obtained. The in-plane absorption coefficients and the thickness agreed with those obtained from independently measured UV-VIS-NIR transmission spectra. (1) Hardaker, S.S., Moghazy, S., Cha, C.Y. and R. J. Samuels, J Polym Sci Part B, 31, 1951 (1993). (2) C. Cha , S. Hardaker, R. Gregory and R. Samuels , Synth. Met., 84 , 743 (1997).

NP01 158 Converse Electrostriction in Polymers and Composites SYLVIE EURY, *MRL., Penn State Univ., University Park, PA 16802 USA.* RATTIKORN YIMNIRUN, *MRL., Penn State Univ., University Park, PA 16802 USA.* PAUL MOSES, *MRL., Penn State Univ., University Park, PA 16802 USA.* V. SUNDAR, *Ceramco., Six Terri Lane, Burlington, NJ 08016 USA.* ROBERT NEWNHAM, *MRL., Penn State Univ., University Park, PA 16802 USA.* Electrostriction is the fundamental mechanism of electromechanical coupling in all insulator materials. The evaluation of electrostrictive properties of low permittivity dielectrics requires extremely sensitive instrumentation. In the present work, the electrostriction coefficients of several polymers were measured by a converse method. A dynamic compressometer was specifically designed to resolve fractional changes in capacitance on the order of 10^{-6} caused by in-phase cyclic uniaxial stresses on the samples. Measurements were done at room temperature with an electrical frequency of 1kHz and a mechanical frequency of 0.4Hz. We found negative electrostriction coefficients for the polymers tested. Trends in the electrostriction coefficients with the structure and the presence of additives in the resins were identified. Moreover we checked that the corrected electrostriction coefficient Q of polypropylene was independent of the electrical frequency in the range 500Hz-100kHz. Using these new data, along with widely accepted data on other materials, the linear relationship between electrostriction coefficient (Q) and the ratio of elastic compliance and the dielectric constant (s/K) was obtained. This relationship leads to an effective way to predict the electrostriction coefficient in dielectric materials. This study was supported through National Science Foundation grant DMR-9634101.

NP01 159 Local and Global Dynamics in Polyethylene and Polypropylene Melts by ^{13}C NMR X.H. QIU, N.E. MOE, M.D. EDIGER, *University of Wisconsin-Madison* We report ^{13}C NMR T_1, $T_1\rho$ and NOE measurements of atactic polypropylene (PP) and polyethylene (PE) melts as a function of Larmor frequency and temperature. We found that the data taken on PP discriminated decisively against two commonly used bimodal distribution functions, the DLM and modified $logX^2$. A trimodal distribution function was required to describe the dynamics, with the third component placed between the fast and slow components of the modified $logX^2$ distribution. Compared to PP, PE has a very pronounced long time tail in the orientation correlation function for C-H bond vectors and the local motions are more anisotropic. We hypothesized the difference to be caused by the lack of side groups on PE which allows C-H vectors to keep some memory of their initial orientation even after many conformational transitions occur. $T_1\rho$ provides the upper and lower limit for the integral of the full correlation function.

NP01 160 Chain Motion in Polyethylene and Related Systems W. HU, K. SCHMIDT-ROHR, J. PENELLE, C. LE FEVERE, *Polym. Sci. and Eng. Dept.* J. MAO, B. XING, *Plant and Soil Sci. Dept., Univ. of Mass. Amherst* The rate of the 180^o flip motion, which leads to the crystalline α relaxation in polyethylene, was determined from 280 to 360 K by solid-state NMR that observes the reorientation of C-C bonds. The activation energy is (93 $\pm$ 10) kJ/mol, consistent with dielectric and dynamic mechanical relaxation. In contrast, in 1,22-docosanediol which has a similar crystal lattice as polyethylene but a different crystal surface structure, a solid-solid phase transition is found at T_r=93^{o}C. Static ^{1}H and ^{13}C NMR show that below T_r the chains have no (or slow if any) large-amplitude mobility, while above T_r they rotate freely. ^{1}H NMR shows that throughout the transition, neighboring regions of the emerging rotator phase are separated by $>$ 100 nm and the mobility of the chains in both phases remains unchanged, consistent with the nucleation and growth model. As in several n-alkanes and ultradrawn polyethylene fibers, a liquid-like phase of 1% - 5 % was observed in the diol well below the melting point. Its possible association with grain boundaries is under investigation. A polyethylene- like crystalline component was found in several soil samples. Based on the Thomson-Gibbs relation, the melting behavior observed by NMR yields crystallite thicknesses of 3-4 nm.

NP01 161 Morphology and Properties of Extrusion Cast Elastomeric Films A. NEEB, *Kimberly Clark Corp. - KCC* O. THOMAS, *KCC* H. HRISTOV, *KCC* A. BRENNAN, *Univ. Florida, MSE* R. DURAN, *Univ. Florida, Chemistry* G. WEERASEKERA, *Univ. Florida, Chemistry* The effects of processing and additives on the structure and properties of two SBS thermoplastic elastomers, are reported. The initial materials contained either 15 wt. diblock copolymer(trade name Kraton D1102, Shell Co., 28 wt.The pellets were extruded by using a single-screw extruder and wound on a quench roll under minimal tension. SAXS results indicate that the morphology of the hard segment (PS) domains in D4150 is hexagonally packed cylinders, i. e. similar to that of the equilibrium structures. It was concluded that the processing oil promotes a rapid microphase separation and ordering. In contrast, the morphology of the extruded specimen D1102 appears to be similar to the fluctuation- induced disordered structures.[1] Annealing at 145 C and slow cooling did not lead to equilibrium ordering of the PS domains. It appears that low molecular weight diblock copolymer inhibits phase segregation and ordering.

[1]See for example N. Sakamoto, T. Hashimoto, Macromol. 31, 3815 (1998).

NP01 162 Analysis of Molecular Parameters Governing Phase Separation in Polyurethanes DORIE J. YONTZ, SHAW L. HSU, *University of Massachusetts, Amherst* It is well established that polyurethanes phase separate into hard domains coexisting with a phase of hard segments dispersed in a soft matrix. However,

previous studies have shown that the interaction energy is negative, indicating that phase mixing is enthalpically favorable. Theoretical work has shown that the driving force for phase separation comes from the orientational entropy associated with the chain rigidity of the hard blocks. The implication is that chain length is crucial in determining the phase separated morphology in polyurethanes. Our current research has focused on a chemically crosslinked polyurea urethane system consisting of an aromatic urea hard segment and a polyether soft segment. We detached the hard segments from the soft segments and used MALDI Mass Spec to characterize the chain lengths of the rigid blocks. We have found that the distribution of chain lengths is quite broad, ranging from 3 to greater than 8 repeat units in a system that theoretically has an average of 4 or 6 repeat units. The impact of hard segment length on morphology and mechanical properties will be addressed.

NP01 163 Response Saturation in the Analysis of Synthetic Polymers by MALDI ROBERT GOLDSCHMIDT, *NIST* CHARLES GUTTMAN, *NIST* Matrix-assisted laser desorption/ionization (MALDI) is one of the most successful mass spectrometric techniques developed to date for the analysis of large and thermally labile molecules. For synthetic polymers, MALDI can yield quantitative information, such as a description of the molecular weight distribution, as well as qualitative information about end groups and repeat units. Accurate quantitative measurements require an equimolar response, or at least a predictable variation in response, for all sample species in the mass range over which the polymer sample is distributed. There are both instrumental and sample-related factors that can influence the relative response of sample species. Some sample-related factors may influence the dispersion of polymer molecules throughout the matrix and so affect the degree of matrix-isolation achieved and whether there is any size-based order to it. To probe this, we examine the influence of polymer loading and matrix choice on the responses of low molecular weight poly(ethylene glycol) and poly(styrene) samples.

NP01 164 The Hydrogen-Hydrogen Inter-molecular Structure of Polyethylene in the Melt* J. D. LONDONO, *E. I. DuPont* B. K. ANNIS, A. HABENSCHUSS, *Oak Ridge National Laboratory* G. D. SMITH, O. BORODIN, *University of Utah* C. TSO, E. T. HSIEH, *Phillips Petroleum Co.* A. K. SOPER, *Rutherford Appleton Laboratory, ISIS* The model-free inter-molecular HH distribution function for PE is extracted from wide-angle (NDIS) and small-angle neutron difference scattering experiments at 428 K, and compared to MD simulations. The inter-molecular HH structure function was obtained without recourse to intra-molecular structure models, and is interpreted on three length scales: 1) the correlation hole which depends on the radius of gyration of the molecule, 2) chain-chain packing, and 3) local HH inter-molecular correlations. These results are significant because they demonstrate that the HH inter-molecular correlation function is useful for studying inter-molecular polymer structure, which has been shown to underpin phase behavior in polyolefin blends.

NP01 165 Surface Initiated Living Cationic Polymerization of 2-Oxazolines on Gold Nanoparticles RAINER JORDAN, *Polytechnic University, Brooklyn NY; Lehrstuhl fuer Makromolekulare Stoffe, Technische Universitaet Muenchen, Germany* YENMING CHOU, ABRAHAM ULMAN, *Polytechnic University, Brooklyn NY, USA; NSF MRSEC for Polymers at Engineered Interfaces* Based on our synthetic concept of preparing dense polymer brushes on planar gold substrates, in which self-assembled monolayers (SAM) of terminal functionalized thiols were used to initiate living cationic ring-opening polymerization [1] we prepared a series of analog reactions using functionalized gold nanoparticles as starting materials. End-functionalized self-assembled monolayers (SAMs) were used to initiate living cationic polymerization reaction directly on the particle interface ('grafting from technique'). In this manner, dense poly(N-propionylethylenimine) (PPEI) polymer brushes of amphiphilic nature as well as Poly(2-phenyloxazoline)[2] were prepared in a 'one-pot multi-step' reaction. ER FTIR spectroscopy confirms the successful polymerization reaction as well as the introduction of terminal functional group. The resulting gold/polymer-nanocomposite was found to be very stable. The combination of a 'grafting from reaction' resulting in preorganized polymer 'brush-type' layers of linear macromolecules and the introduction of a terminal mesogene, providing further order based on the hydrophilic/lipophilic balance (HLB), offers the possibility to create significantly thicker layers responding to environmental stimuli in a well-defined fashion. This strategy provides a facile way for the preparation of dense functional polymer brushes for applications in biotechnology and the development of sensor devices. [1] R. Jordan, A. Ulman : J. Am. Chem. Soc. 120 (1998) 243-247. [2] Y. Chou, A.Ulman, R. Jordan: in preparation.

NP01 166 Atomistic Modeling of Liquid Crystalline Phases SOUMYA S. PATNAIK, RUTH PACHTER, *Materials and Manufacturing Directorate, Air Force Research Laboratory, WPAFB, OH* Recently many molecular dynamics (MD) studies of thermotropic liquid crystals have been carried out using atomistic models. These models allow for a detailed description of the molecular structure and are essential for a quantitative study of liquid crystalline properties, which are very sensitive to the molecular details. The aim of the current study is to investigate the effect of the system size (which often limits such calculations) and the shape of the periodic cell on the evolution of the mesophase during the MD simulation. We have focused on 4-n-pentyl-4'-cyanobiphenyl (5CB) in the nematic phase. The equilibration time required for the evolution of the mesophase was also estimated for different initial conditions.

NP01 167 Healing of Sheared Confined Films Following Large-Amplitude Deformation YINGXI ZHU, *University of Illinois at Urbana-Champaign* STEVE GRANICK, *University of Illinois at Urbana-Champaign* Polydimethylsiloxane (PDMS) chains of variable molecular weight were confined between mica sheets in a surface forces apparatus modified for the application of shear. The film thickness was of order 5 nm. First the films were deformed for 30 min at constant shear rate by the application of force impulses with triangular waveforms. The resulting nonequilibrium surface structure was probed by the subsequent application of small-amplitude sinusoidal shear, and the measurement of the in-phase (elastic) and out-of-phase (dissipative) components of the resulting deflection. It emerged that the films healed over times lasting of order several hours. Immediately following the strong shear the dissipative response exceeded the elastic response, but following the cessation of strong shear the elastic response grew

more quickly with elapsed time than the dissipative response. The kinetics of these processes could be described as proportional to the square root of elapsed time – suggesting that the healing process stemmed from the interdiffusion of two initially-distinct sheared layers.

NP01 168 Diffusive Transport in and Development of Polymer Membranes for Immunoisolation D.R. BOGGS, J.M. TORKELSON, *Northwestern Univ., Evanston, IL 60208-3120 USA* The encapsulation and implantation of living cells for the treatment of disease, such as diabetes via an implantable membrane device containing insulin-secreting tissue, is an exciting biotechnology. A major challenge is membrane development which permits passage of O2, glucose and insulin yet excludes large immune factors causing graft rejection. Membrane development and characterization for immunoisolation was studied. A multi-station diffusion test system was designed and characterized for boundary layer effects. Diffusion of vitamin B12, myoglobin, albumin, IgG and dextran were measured by Taylor dispersion. Multi-solute test methods were used with polydisperse dextran and biological markers. Membranes were made from cellulose acetate, cuprammonium cellulose, and poly(ethylene-co-vinyl alcohol) and their diffusive permeabilities measured. Small-solute permeability was achieved, but low permeability to larger solutes was not, likely due to a small number of large pores determining large-solute transport.

NP01 169 A Monte Carlo Simulation of Polyethylene Melts between Two Attractive Plates, with Pulling of the Plates. JEE H. JANG, *University of Akron* WAYNE L. MATTICE, *University of Akron* The dynamics of C120 and C60 polyethylene melts between two attractive plates, with pulling of both plates at various speeds, has been studied by using a Monte Carlo simulation on a high coordination lattice [1]. At each pulling speed, C120 and C60 showed quite different density profiles in such a way that the faster pulling resulted in the higher density in the middle region between the plates. It was also found that the dependence of the density on the speed was much more prominent in the case of C120, which can be considered to be close to entangled system. The total attractive energy between the plates and chains increased rapidly at the faster pulling, while it remained constant at the slowest pulling. This dependence is in accordance with the experiment of elongational viscosity on polyethylene melt [2]. These results have been analysed in terms of three main processes during the pulling, attachment/detachment of chains on the plates, chain relaxation, and development of entanglement. Supported by NSF grant DMR 95-23278. 1. Rapold, R. F.; Mattice, W. L. J. Chem. Soc. Faraday Trans. 1995, 91, 2435 2. Meissner, J. Rheol. Acta 1971, 10, 230

NP01 170 Local and Electronic Structure of Vitamin B12: X-ray Fluorescence Measurements M. MATTEUCCI, *Institute of Condensed Matter, Italy* E.Z. KURMAEV, *Institute of Metal Physics, Russia* A. MOEWES, *CAMD/LSU* B. SCHNEIDER, *University of Osnabrueck, Germany* V.R. GALAKHOV, *Institute of Metal Physics, Russia* M. NEUMANN, *University of Osnabrueck* L. RANDACCIO, *Universita di Trieste, Italy* The results of fluorescence measurements of Co L2,3 and F Ka X-ray emission spectra (XES) from vitamin B12 are presented. The data are compared with spectra of reference samples: Co, CoO, LiCoO2, CoF2 and AlF3. A single crystal of vitamin B12 was obtained by adding KF to a water solution of cobalamin. According to X-ray diffraction measurements, this crystal is an octahedral Co complex with five coordination sites occupied by a large macrocycles (corrins) and the sixth by either OH or F ligand. The analysis of the emission spectra shows that Co-F bonds are formed indicating that fluorine is the sixth ligand of this compound. The Oxidation State of Co ion is found to be Co3+.

NP01 171 Experimental and molecular modeling study of polyelectrolyte gels DANILO GONZALEZ-NILO,* *Universidad de Santiago de Chile, Faculty of Chemistry and Biology* LEONOR CONTRERAS,† *University of Santiago de Chile, Faculty of Chemistry and Biology* RAUL CACHAU,‡ *Advanced Biomedical Computing Center, National Cancer Institute* UNIVERSITY OF SANTIAGO DE CHILE, FACULTY OF CHEMISTRY AND BIOLOGY COLLABORATION, ADVANCED BIOMEDICAL COMPUTING CENTER, NATIONAL CANCER INSTITUTE COLLABORATION, Polymeric gels (PGs) are ubiquitous and versatile materials with applications ranging from the oil to the medical industries. The development of improved PGs resulted in PGs of more complex constitution and new chemical composition. These efforts have been led by random screening of materials. The structure and conformation of the polymer chain control the PGs properties. Another approach towards improved PGs proceeds through the study of PGs structural features. In absence of experimental structural information modeling techniques can be used to describe structural details of PGs. Various techniques have to be applied, in order to fully characterize the structure of PGs. In this work swelling and shrinking of PGs are studied using molecular modeling and experimental techniques. PGs show a significant volume variation with changes in the external solution composition, the temperature, osmotic pressure, or electrical field. Gels of acrylic acid (AA) were synthesized and characterized for this study. The swelling of the gel was measured at different crosslinker contents and for different pH values. Structural correlations for these processes were established using molecular modeling studies. These studies included molecular dynamic simulations using as a model a crosslinker molecule (N, N'-Methylenebisacrylamide) having bounded to each of its four extremes segments constituted by eight monomer units each. Periodic boundary conditions with explicit water molecules were used to complete the model. This model was used to study the monomer-solvent interaction along the polymer chain. An extension of this study using alternative modeling techniques will also be presented.

NP01 172 Incorporation of Polyelectrolyte Complexes into Multilayer Assemblies CHRISTOPHER J. BARRETT, MICHAEL F. RUBNER, ANNE M. MAYES*, *Department of Materials Science and Engineering, MIT* T. ALAN HATTON, *Department of Chemical Engineering, MIT* The sequential adsorption of molecular layers of polyelectrolyte onto charged substrates has been established as a promising route to the fabrication of stable thin film multilayer structures. The thickness of each layer deposited can be controlled by varying the adsorption parameters, but only to an upper limit of approximately 100 Angstroms. Beyond this thickness limit one requires alternative techniques for incorporating layers of polyelectrolyte into multilayer structures. Here we report the use of soluble complexes of polycation and weakly-charged polyanion, which can be readily adsorbed onto the surface of multilayer structures from dilute solution to yield stable

and uniform layers in the thickness regime of 100 to 1000 Angstroms. Solution properties of the complexes were studied by light scattering and compared with the properties of the adsorbed layers, as studied by ellipsometry and neutron reflectivity.

NP01 173 Comprehensive Study of Conformational, Thermodynamic and Rheological Properties of Binary and Ternary Polymer Solutions R. V. FIGINI, T. S. GRIGERA, I. M. IRURZUN, M. MARX-FIGINI, M. S. CORTIZO, *INIFTA, Universidad Nacional de La Plata, Argentina* In going from the dilute to the semidilute regime, the progressive coil overlapping gives rise to a gradual screening of both hydrodynamic and excluded volume interactions, while at the same time making topological interactions among different chains possible. These effects strongly affect all properties of the solutions, and in recent years, different theoretical approaches based in renormalization group theories have been developed to account for them. However, a simultaneous analysis, including static and dynamic properties is not yet available. In this work, we present a comprehensive study of conformational, thermodynamic and rheological properties of semidilute polymer solutions in good solvent. The description of our experimental data is made combining the de Gennes's reptation model with Schafer's RG results. This analysis allows to take into account the polydispersity influence and can be extended to the interpretation of properties of ternary an quaternary polymer solutions.

NP01 174 A Simple Relation for the Solubility of Gases in Polymers JOANNE L. BUDZIEN, *New Mexico Institute of Mining and Technology* JOHN D. McCOY, *New Mexico Institute of Mining and Technology* JOHN G. CURRO, *Sandia National Laboratory* RANDALL A. LAVIOLETTE, *Idaho National Engineering and Environmental Laboratory* The polymer reference interaction site model theory is applied to gas solubility in polyethylene-like polymers. With a few simplifications, the single site type model can be extended to other polymers. Using only the monomer structure and some gas solute properties, reasonable predictions of the gas solubility of various polymers can be made. The resulting predictions are compared with experimental data and the simplified solubility equation is compared to the Flory-Huggins form.

NP01 175 Thermal enhancement of AFM phase contrast for imaging diblock copolymer morphologies MICHAEL J. FASOLKA, PALLAB BANERJEE, ANNE M. MAYES*, *Dept. Materials Science and Engineering, MIT* Atomic Force Microscopy (AFM) has become a standard tool for imaging the microphase separated morphologies of block copolymers. Particularly useful in this endeavor is so called ''phase'' imaging, which elucidates local elasticity differences in the sample surface. At room temperature, phase imaging some block copolymer morphologies can be problematic. If each of the block components is below its glass transition temperature, there may be little or no elasticity difference between them. Accordingly, there will be little contrast in the phase image, and little morphological information will be conveyed. Recently, we have developed a simple scheme for dramatically increasing the phase contrast in AFM micrographs of polystyrene-b-(n-alkyl methacrylate) diblock copolymers. At room temperature, both block components are below their glass transition. By heating these materials to a point between the glass transition temperatures of polystyrene and the methacrylate block, the latter becomes rubbery while the f ormer remains glassy. Thus, an elasticity difference between the block domains has been created, which imparts added contrast to the phase imaging, adding remarkable detail to the resulting AFM micrographs.

NP01 176 Structure Formation in Polymer Blends in an Electric Field NIKOLAOS BENTENITIS, SONJA KRAUSE, *Chemistry Department, Rensselaer Polytechnic Institute, Troy NY 12180* When a droplet from one phase of a phase separated solution of two immiscible homopolymers is injected in the matrix of the other phase and a homogeneous electric field is applied, the droplet can deform either parallel or perpendicular to the electric field direction. The direction of the deformation has been predicted by Taylor[1] and Torza et al.[2] in terms of the Leaky Dielectric Model (LDM). The LDM has been extended to accurately predict large deformations, as commonly observed in polymer-polymer-solvent systems. An approximate solution has been obtained in spheroidal coordinates. To test the extended theory, experiments with different systems have been conducted and comparison with theory was done using uncertainty analysis. (Supported by NSF, DMR-9521265)

NP01 177 Determination of the Optical Refractive Index of PS Thin Films X. HU, K.W. SHIN, M. RAFAILOVICH, J. SOKOLOV, *SUNY@Stony Brook* Y. CHAN, *Wheatly High School* R.S. STEIN, *U. of Mass@Amherst* R. KOLB, *Exxon* To calculate the optical refractive index of thin film, we used X-ray reflectometer and optical ellipsometry. We used X-ray reflectivity to measure the exact thickness of ps films and ellipsometry to calculate the optical refractive index. Thin film coatings are commonly used to optically match the refractive index of lenses and minimize reflections in optical components. Consequently it is of interest to know whether the refraction index of a polymer is affected by film thickness and processing method. We therefore studied monodisperse polystyrene films after spin coating from toluene solution onto Si wafers before and after annealing. The thickness of thin films studied ranged from 30 to 1000Å, and the Mw ranged from 90 to 2650k. The results show that prior to annealing, the index of refraction is a parabolic function of film thickness, with a maximum at 1000Å. The minimum value measured 1.3 at 30Å and the bulk value was achieved only for films thicker than 2000Å. No significant dependence on Mw was detected. The index of refraction of the annealed film was much less sensitive to thickness and averaged Nu=1.59. Larger deviations were detected for blue light than red light. These results are interpreted in term of internal strain in the spin coated film, which relax upon annealing.

NP01 178 Phase Structure and Dynamics of Crown-Ether-Based Polyrotaxanes K NAGAPUDI, *Georgia Institute of Technology* J LEISEN, *Georgia Institute of Technology* H BECKHAM, *Georgia Institute of Technology* Solid-state NMR was used to examine structure and dynamics of crown-ether-based polyrotaxanes. For poly[$(acrylonitrile)_n$-rotaxa-$(60\text{-crown-}20)_x$] with x/n = 0.01, the crown was found to be phase-separated, amorphous, and highly mobile (albeit showing the presence of more than one dynamic environment) at room temperature. Dipolar magnetization transfer experiments revealed typical smallest diameters of 6 to 8 nm for the 60-crown-20 domains, with interfacial regions of 2 to 4 nm. The interface was attributed to crown segments in contact with PAN as required by the threaded architecture; a physical blend of PAN and 60-crown-20 was phase-separated with a sharper interface than the polyrotaxane. The NMR long periods compared favorably with electron-density correlation lengths from SAXS data. Linear aliphatic polyurethane-rotaxanes were synthesized with 36-crown-12. For this system, new loss peaks appeared

in the dynamic mechanical spectrum (DMS) as compared to the unthreaded backbone. Interpretation regarding the molecular origin of the loss processes was provided by comparing DMS with solid-state NMR and dielectric spectroscopy.

NP01 179 Effects of Solution Concentration and Spinning Voltage on Electrospun Poly(ethylene oxide) Nanofiber Textiles J. DEITZEL, N. BECK TAN, J. KLEINMEYER, M. McQUAID, *US Army Research Laboratory, AMSRL-WM-MA, Aberdeen Proving Grounds, MD 21005* Electrospinning is a process which uses an electric field applied to a polymer solution to produce continuous fibers with diameters in the 10-500 nanometer range. The technique is experiencing a resurgence in popularity due to the recent commercial success of nanofibers in textile and filtration applications. Although it is well established that electrospinning produces nanofibers, very little information is available relating processing variables to the quality of electrospun fibers. In this study, the effects of two such variables, solution concentration and spinning voltage, on the properties of electrospun poly(ethylene oxide) nanofiber textiles have been explored. The defect density in fiber mats is found to be strongly coupled with spinning voltage. A power law relation has been found between solution concentration and fiber size, and a bimodal distribution in fiber diameters has been observed above a critical lower concentration limit. The phenomena has been correlated to similar behavior observed in electrospray processing of droplets.

NP01 180 The Roles of Diffusion and Chain Transfer in Determining the Strength of the Gel Effect in Free Radical Polymerization B. CHEKAL, J.M. TORKELSON, *Northwestern Univ.* Recent studies reveal that the gel effect (autoacceleration) in bulk methyl methacrylate radical polymerization is unrelated to entanglements and instead is dominated by diffusion-controlled termination of the shortest radicals present in great number. Here we show that as the polymer concentration dependence of chain diffusion is a function of chain length, the strength of the gel effect is also a function of the molecular weight of the polymer produced, and we extend our model to molecular weight determination. We also compare the gel effect response among alkyl methacrylates. As alkyl length increases, the gel effect weakens. Modeling of butyl and lauryl methacrylate reactions reveal that, even if termination were dominated by the concentration dependence of monomer diffusion, this would be too strong an effect to explain the autoacceleration. Styrene exhibits similar behavior. We explain these weak gel effect systems based on a combination of diffusion-controlled termination mitigated by the role of chain transfer (resulting in retardation of the reaction) in the longer alkyl methacrylate and styrene systems.

NP01 181 Stability of Thin Film Nanocomposites of Polymers and Organically Modified Layered Silicates RATCHANA LIMARY, PETER F. GREEN, *Department of Chemical Engineering, The University of Texas at Austin, Austin, TX 78712 The University of Texas at Austin Austin, TX 78712* The stability of thin film nanocomposites comprised of organically modified layered silicates (OLS) and OLS/polystyrene-b-polymethylmethacrylate (PS-b-PMMA) was examined using atomic force microscopy. The lateral homogeniety of the OLS/polystyrene-b-polymethylmethacrylate was readily disrupted above the glass transition temperature. Notably, the block copolymer chains were self assembled in the vicinity of the OLS structures while diblock chains on the substrate in regions away from the OLSs became unstable and locally dewet the substrate. In the absence of the OLS structures, the block copolymers remain self assembled on the substrate. The kinetics of the dewetting of the copolymer were determined to be logarithmic.

NP01 182 Aggregation effects on the photophysics of tetrathienylene vinylene PAUL A. LANE, ASHLEY J. CADBY, SIMON J. MARTIN, DONAL D. C. BRADLEY, *Department of Physics and Astronomy, University of Sheffield, UK* JONATHAN PARTEE, JOSEPH SHINAR, *Ames Laboratory and Department of Physics and Astronomy, Iowa State University* The photophysics of tetrathienylene vinylene (4TV) have been studied by absorption, electroabsorption, photoinduced absorption and optically detected magnetic resonance (ODMR). Blends of 4TV in PMMA can be thermally processed so that an isolated or a strongly aggregated state is produced. The absorption spectrum of the isolated state has a 0-0 transition at 2.55 eV with clear structure. Aggregation results in Davydov splitting and new absorption peaks are seen at 2.28 and 3.48 eV. The ODMR magnitude increases linearly with excitation power and also increases with the 4TV concentration. We conclude that recombination is monomolecular and that intermolecular interactions signficantly affect photoexcitation dynamics and yield.

NP01 183 Entropic Elasticity of Single Macromolecules of Wheat Gluten Protein Measured by Atomic Force Microscopy CHRISTINE ORTIZ, ERIC VAN SWIETEN, GEORGES HADZIIOANNOU, GEORGE T. ROBILLARD, *University of Groningen* High molecular weight (HMW) wheat gluten proteins play an important role in the viscoelasticity and baking of dough. One part of the central repetitive domain of this protein was subcloned (denoted dB1) and found to exist in a β-spiral structure, $\sim$ 15 nm in length and $\sim$ 1.5 nm in diameter[1]. Here we have used the technique of single molecule force spectroscopy (SMFS) to study the mechanical denaturation and the entropic elasticity of single chains of dB1. The protein was fixed covalently by one chain end to a substrate and then tethered to an atomic force microscope Si_3N_4 probe tip via non-specific, physisorption interactions. Upon retraction of the probe tip from the surface, continuous, attractive peaks in the force versus distance profiles are frequently observed due to the entropic resistance of uncoiling of the individual chains. These peaks could be fit, for all chain bridging lengths, to the (inextensible) freely-jointed chain (FJC) model. From these datafits a statistical segment length of 0.5 nm was obtained, suggesting incomplete denaturation and a significant portion of H-bonded β-turns still in tact.

NP01 184 Study of the viscosity peak of polyelectrolytes in low ionic strength aqueous solutions DAVID NORWOOD, *Southeastern Louisiana University* CATHERINE DIBENEDETTO, *Southeastern Louisiana University* Polyelectrolytes are polymers that develop a high charge in solution. They include examples of technical interest (such as xanthan, a very stiff polyelectrolyte used as a thickener in food and other products) as well as biological interest (such as hyaluronan, a flexible polyelectrolyte found in, for example, connective tissue and the eye). Viscometry is a powerful polymer characterization technique, but extraction of polymer characteristics is frequently model dependent. Thus, it is of interest to experimentally constrain theories that model the viscosity of dilute polymer solutions in terms of the properties of the polymer molecules. It has long been known that the reduced viscosity of polyelectrolytes in low ionic strength solution presents a

peak as a function of concentration[1]. Some models seek to explain this in terms of interactions of the polyelectrolyte molecules with other charges. Other theories explain the peak in terms of changes in the conformation of the polyelectrolyte. We present measurements of the viscosity of a very stiff polyelectrolyte (xanthan, with a persistance length of about 1500 Å)[2] at very low added salt. The stiffness of xanthan minimizes conformation changes, permitting an investigation of the differences between the various models.

NP01 185 Thermoreversible Gelation of Aqueous Poly(vinyl alcohol) Solutions* D.A. HOAGLAND, D.W. HOWIE, P.J. WILLCOX, K. SCHMIDT-ROHR, S.P. GIDO, *Polym. Sci. and Eng., U. of Mass. Amherst* As an aqueous poly(vinyl alcohol) solution is cooled near and below room temperature, the solution slowly phase separates. If the polymer molecular weight and concentration are sufficiently large, the result of phase separation is a gel. A gel of similar modulus and pore size can be created more rapidly if the same solution is quenched below the freezing point of water and then thawed. Additional freeze/thaw cycles increase the modulus. To understand gelation and gel microstructure, we have used small angle X-ray and light scattering, solid-state NMR, cryogenic TEM, DSC, and optical microscopy. We believe that the formation of small, 5-10 nm crystallites induces solidification, with several percent of polymer segments involved; this percentage rises with aging or thermal cycling. Crystallite crosslinks are separated by approximately 20 to 40 nm on a random mesh with intervening amorphous segments. Ice crystallization and spinodal-like phase separation before gelation may superimpose larger, micron-sized microstructural features on the gel.

*ALZA is acknowledged for financial support.

NP01 186 Transport Tensors for a Wormlike Chain SERGIO R. ARAGON, *San Francisco State University* The transport tensors (translational diffusion and rotational diffusion) for wormlike chains have been computed by averaging over a large Hagerman-Zimm ensemble of rigid linear bead shapes (statistical precision to .2/100). The calculations were done as a function of both axial ratio (number of beads) and the number of persistence lengths in the chain. The hydrodynamic calculations have been carried out with a high precision program which takes into account translation-rotation coupling and the rotation-rotation terms between pairs of beads, and other bead effects on the self diffusion terms.[1] The inclusion of this type of terms permits the accurate calculation of tensors even for the completely straight bead array. The tensors are represented by interpolation formulas for axial ratios up to 100, and contour length to persistence length ratio up to 10. These tensors are useful in interpreting experiments such as electric birefringence, dynamic light scattering and fluorescence polarization anisotropy that are sensitive to the dynamics of the wormlike chain. They are also useful in the study of simulations carried out with bead representations of wormlike chains.

[1]R. Goldstein, J. Chem.Phys. 83,2390 (1985)

NP01 187 Phase Behavior and Unusual Macroscale Order in Styrene/n-Alkyl Methacrylate Diblock Copolymers A.-V. RUZETTE, *MIT* P BANERJEE, *MIT* A. M. MAYES, *MIT* M. POLLARD, *UMASS, Amherst* T. P. RUSSELL, *UMASS, Amherst* In an attempt to identify the molecular origin of the lower critical ordering transition (LCOT) in polystyrene-block-poly n-butyl methacrylate, the phase behavior of copolymers formed from styrene and a homologous series of n-alkyl methacrylates was investigated. It was found that the thermodynamic compatibility between the two blocks and the resulting phase behavior strongly depend on the degree of branching of the methacrylate block. This same structural parameter also seems to influence the viscoelastic properties of the copolymers and their tendency to align under external flow fields when in the ordered state. In fact, abnormally large degrees of alignment of the lamellar microdomains were observed in some symmetric copolymers after processing steps as trivial as compression molding. This strong tendency to align under minor stresses or strain fields appears extremely advantageous from an engineering standpoint, as it could yield a host of new materials in which macroscopic alignment and directional properties can be induced via standard polymer processing steps. The possible origins of such behavior and its implications from a processing standpoint will be discussed.

NP01 188 Molecular Dynamics Simulation of Poly Vinylidene Floride (PVDF) OLEKSIY G. BYUTNER, GRANT SMITH, *Department of Materials Science and Engineering, University of Utah* We present a new ab initio based force-field for molecular dynamics simulations of poly(vinylidene floride), PVDF. It was obtained using Hartree-Fock geometries (D95**) and MP2 energies (D95+**) of four molecular compounds: 1,1,1,3,3 – pentafluorobutane, 2 molecular dimers – 1,1,1,3,3,5,5,5-octofluoro- and 2,2,4,4-tetrafluoropentane, and a molecular trimer – 2,2,4,4,6,6-hexafluoroheptane. The conformational energy contours reveal that the $-CF_2-CH_2-CF_2-CH_2-$ torsion is split in both the trans and gauche states and has a lowest energy state at gauche (65°). These conformational characteristics are fully represented by a six-state rotational isometric state (RIS) model comprised of all six possible states, located at the split energy minima. Preliminary molecular dynamics simulations of amorphous PVDF were performed at temperatures higher than melting point (439 K) and yield PVT and conformational properties with available experimental data.

NP01 189 Gibbs-DiMarzio Theory for the Tg Behavior of Polymer Thin Films ERIC LIN, *National Institute of Standards and Technology (NIST)* DARRIN POCHAN, *NIST* WEN-LI WU, *NIST* Changes in the glass transition temperature (Tg) for very thin polymer films have been measured using a wide range of experimental techniques. The polymer Tg has been observed to increase or decrease depending upon whether or not the film is supported on a solid substrate and the nature of the interaction between the polymer and the substrate. To date, few theoretical approaches have been undertaken to complement the extensive experimental effort. In this work, the Gibbs-DiMarzio criterion of a vanishing configurational entropy at Tg for polymers is adapted for the thin film geometry. The configurational statistics are evaluated using a self-consistent mean field model. The effect of the polymer chain length, bending energy, and surface interaction energy on the calculated Tg and the polymer configurations within the film will be presented and discussed in relation to data from recent X-ray and neutron reflectivity experiments.

NP01 190 The Effects of Surface Interactions on Phase Segregation SHAOMING ZHU, GERSAPPE DILIP, MIRIAM RAFAILOVICH, JONATHON SOKOLOV, RICHARD GAMBINO, *Dept. of Materials Science and Engineering, SUNY at Stony Brook, NY11794-2275* ANDY WINESETT, H ADE, *Dept. of Physics, North Carolina State University, Raleigh, NC2769* ROBERT DINARDO, *Instrument Division, Brookhaven National Laboratory, Uptown, NY11973* The effects of the surface interactions on the phase segregation of Polystyrene(PS)/ Poly(methyl methacrylate)(PMMA) was studied. Film of symmetric blends of

PS(Mw=90k) and PMMA (Mw=27k) were spun cast onto Au, Co, Si and patterned substrates. The samples were analyzed using both Scanning Transmission X-ray Microscope (STXM) and Scanning Force Microscopy. The patterned surfaces were made by printing Au,Co and Sistructures approx. 300Å high with a specific wave vector onto a silicon wafer. The results on the flat surface show that the morphology is determined by the polymer which wets the surface. On the patterned surface the extent of phase segregation can be controlled by the wave vector of the pattern. This may be a potential mechanism in phase stabilizing polymer blend film on surface. Acknowlegement:We appreciate the support of the National Science Foundation Polymer Program-(DMR9316157), the Department of Energy(DE-FG02-93ER45481), and the MRSEC program of the National Science Foundation(DMR9632525)

NP01 191 Self Assembly of Islands/Holes in Diblock Copolymer Films Under the Influence of a Confinement Layer with a Thickness Gradient* M. HAMMOND, J. HEIER, E.J. KRAMER, *UCSB* We cast symmetric poly(styrene-b-2vinylpyridine) (PS-PVP) diblock copolymer thin films on Si which form lamellae oriented parallel to the substrate surface, with equilibrium thicknesses 1.5 L_0, 2.5 L_0, etc. where L_0 is the lamellar period. We investigate films of initial thickness 2.0 L_0, which form bicontinuous structures of domains with either 1.5 or 2.5 L_0 thickness after annealing. Preannealing such films under a $\sim$ 100 nm thick confinement layer of a third, glassy polymer restricts island/hole formation and causes the chains in the lamellae to stretch. If there is a thickness gradient in the confinement layer, however, we observe a grating structure after a final anneal with no confinement that consists of alternating stripes of PS-PVP film thickness $1.5L_0$ and $2.5L_0$. The stripes of this grating are perpendicular to the gradient of the confining film thickness, indicating that stripe orientation results from the stiffness anisotropy of the confining film.

NP01 192 Optical Properties of Carbon Nanotube-PMMA Composites D. CARROLL, *Department of Physics and Astronomy, Clemson Univeristy* R. CZERW, *Department of Physics and Astronomy, Clemson Univeristy* S. HOSHI, *Department of Physics and Astronomy, Clemson Univeristy* D. BENENTI, *Department of Physics and Astronomy, Clemson Univeristy* E. GREGORY, *Department of Physics and Astronomy, Clemson Univeristy* D. TARBOX, *Department of Physics and Astronomy, Clemson Univeristy* J. BALLATO, *Department of Ceramics and Materials Engineering* P. AJAYAN, *Department of Materials Science and Engineering, Renssealer Polytechnic Institute* Carbon Nanotube-PMMA (Polymethal Methacrylate) composites have been formed though a new dispersion process. This process utilizes surfactant separation of nanotubes and ultrasonic mixing to achieve near ideal dispersion of tubes within the polymer matrix. We will present recent results on the optical properties of such composites which include broad band optical limiting and nonlinear optical scattering due to nanotube alignment. Further, we demonstrate the fabrication of optical fibers and fiber coatings from this material and the result of nanotube alignment in fiber mode structure.

NP01 193 Excited State Study of Thiophene, Cyclopentadiene and Fulvene Based Polymers J.B. LAGOWSKI, D. CHAKRABORTY, H. SUBRAMANIAN, *Memorial University of Newfoundland** Excitation energies of polythiophene, polycyclopentadiene and polyfulvene and their cyano-bridged derivatives are analyzed with the use of model compounds. We employ ab initio, configuration interaction (singles) approach (CIS) with 3-21G* and 6-31G* basis sets to investigate excited state (singlets) energies and structures of stable thiophene, cyclopentadiene, fulvene and their cyano-bridged oligomers (monomers to octamers). The results of CIS/3-21G* calculations predict substantial structural changes in the backbones of (aromatic or quinoid) oligomers in comparison to their ground state geometries. For small oligomers, these changes are sensitive to the size of the oligomer. Trends in structures, especially as related to bond alternation, will be discussed extensively. In agreement with previous studies, this investigation gives strong theoretical evidence that the cyano substituted compounds have considerably smaller intrinsic band gaps then their respective unsubstituted parents.

*Research Supported by National Science and Engineering Research Council of Canada.

NP01 194 Correlation of the scope of sub-T_g molecular motion with the ductility of polymers based on SBI X. LI, A.F. YEE, *Macromolecular Science and Engineering Center, University of Michigan, Ann Arbor, MI 48109* Main chain sub-T_g molecular motion is strongly correlated with the toughness of polymeric materials. Chair-boat-chair (CBC) transitions of cyclohexane rings (C rings) in the polymer chain can enhance cooperative molecular motions and thus improve mechanical proerties. The *extent* to which C ring CBC transitions can enhance the cooperative motion is not known. In order to answer this question, we incorporate a unique monomer SBI into polymer chains. The chemical structure of SBI (3,3,3',3'-tetramethyl-1,1'-spirobiindane) differs significantly from that of bisphenol-A. The phenyl rings in SBI are locked, eliminating rotational degrees of freedom and thus providing a unique probe. Polymers with different structural lengths between consecutive SBI units have been synthesized. DMA, Positron Annihilation Lifetime Spectroscopy (PALS), and mechanical tests have been used to characterize these polymers. The results show that the cooperative motion of C rings and BPA can make inherently brittle SBI polycarbonate ductile. This cannot be achieved with CBC transitions alone. The results suggest that in order for the polymers to yield, cooperative motion involving at least a couple of structural units may be necessary. Work supported by the AFOSR (grant F49620-98-1-0158).

NP01 195 Secondary Crystallization Kinetics of Poly ether ether ketone HERVE MARAND, *Virginia Tech* AZAR ALIZADEH, *Virginia Tech* RAVI DESAI, *Virginia Tech* ROBIN FARMER, *Virginia Tech* VESSELIN VELIKOV, *Virginia Tech* The multiple melting behavior of poly[ether ether ketone] (PEEK) has been investigated in detail. Specifically, we have studied the effects of heating rate, crystallization time and temperature on the evolution of the high and low endotherms recorded subsequent to isothermal crystallization, from the melt or from the glass. Our results indicate that PEEK behaves in a very similar fashion to polycarbonate, and to some extent to ethylene copolymers (i.e. the multiple melting behavior is due to the melting of separate population of crystals, lamellar and fringed micellar). We also showed that, secondary crystallization whether occurring subsequent to cold or to melt crystallization is characterized by a unique mechanism. Secondary crystallization leads to a shift of the material relaxation spectrum to longer times as a result of increased constraints in the remaining amorphous fraction. Correlations between the upward shift of the low endotherm and the glass transition temperature with increase in crystallization time provides strong support to our speculation that the upward shift of the low endotherm location is associated with a steady decrease in the configurational entropy of the remaining amorphous fraction during secondary crystallization.

NP01 196 Investigation of the Nanofibrils of Silk Fibers SIRINA PUTTHANARAT, *The University of Akron* RONALD EBY, *The University of Akron* Silk from Bombyx mori as well as other silks have been investigated using Atomic Force Microscope (AFM) and Scanning Electron Microscope (SEM). A range of morphological features including nanofibrils, bundles of nanofibrils and a layered structure with a cross angle between nanofibrils in different layers was observed for all silks. The average width of the fibrils is about 110-190 nm. While there is no correlation between the size of silk fiber and the size of fibrils from different species of silkworm, there is a correlation along the length of the single fiber in the cocoon for a given silk. The cross angle is in the range of 30-50 degrees. A simplified computer calculation method has been used to obtain the possible angles which minimize the interaction energy of packing between beta sheets of silk. Wide angle X-ray diffraction (WAXD) measurements are used in an attempt to determine the fraction of fibrils at different cross angles. All the results are qualitatively consistent with the hypothesis of fibril formation by crystal nucleation and orientation by epitaxy.

NP01 197 Study of structural & morphological changes of polypropylene fibers during deformation by WAXD/SAXS DUFEI FANG, *Chemistry Department, State University of New York at Stony Brook* SHAOFENG RAN, *Chemistry Department, State University of New York at Stony Brook* XINHUA ZONG, *Chemistry Department, State University of New York at Stony Brook* BENJAMIN HSIAO, *Chemistry Department, State University of New York at Stony Brook* BENJAMIN CHU,* *Chemistry Department, State University of New York at Stony Brook* The solid state deformation of fibers by drawing leads to a considerable enhancement of their mechanical properties in the elongation direction. This improvement of the macroscopic properties has a close relationship with the change of the structure and morphology in the fibers. Further more, the processes of fibers such as drawing and heat treatment are dynamic, during which structure and morphology are changing continuously. Therefore it is important to study these changes of fibers in real time during deformation. Wide angle X-ray diffraction (WAXD) and small angle X-ray scattering (SAXS) is the most important technology to do the on-line characterization of these changes[1,2]. In this work, an industrial prototype drawing machine is placed into the X3a2 beam line of NSLS to do the on-line WAXD/SAXS determinations of the polypropylene fibers at different drawing conditions. Here we present the high quality two-dimentional WAXD/SAXS image patterns of deformed fibers. A comprehensive analysis software (XDPP) is used to obtain a quantitative result of the structural and morphological changes of the fibers. The results show that the drawing ratio has more effects on the structural and morphological changes of fibers than the drawing temperature and the drawing speed. NP01 198 Effect of compositional fluctuations on the cure kinetics of network polymers R. SY-SIONG-KIAO, *Purdue University* J.M. CARUTHERS, *Purdue University* Network polymers are produced by curing two or more multifunctional reactive monomers in order to form a three-dimensional network. A basic assumption in the analysis of cure kinetics of the system is that its composition is homogeneous; hence, concentrations of the reactants do not vary across the system. With this assumption, reaction order obtained from the analysis of the cure kinetics should be of elementary order. However, contrary to the model, experimental data always resulted in fractional order kinetics. The assumption of homogeneous composition is correct for as long as the system is capable of large scale mixing. However, as the reaction proceeds the formation of the network will hinder the large scale mixing permitting only mixing in local region, which may be sufficiently small that fluctuations in local monomer composition are significant. A model that incorporates the effect of local composition fluctuations in a mesoscopic domain after the cessation of macroscopic mixing has been developed to explain the fractional kinetic reaction order obtained by traditional analysis. The model shows that although the reactions are elementary, the local compositional fluctuation could result in an overall fractional kinetic reaction order.

NP01 199 Epitaxial crystallization of triblock copolymers onto benzoic acid CLAUDIO DE ROSA,* *Department of Material Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139* CHEOLMIN PARK, *Department of Material Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139* EDWIN L. THOMAS, *Department of Material Science and Engineering, Massachusetts Institute of Technology, Cambridge, MA 02139* Epitaxial crystallization of polyethylene blocks (PE)in ethylene-b-(ethylene-alt-propylene)-b-ethylene (PE/PEP/PE) and styrene-b-(ethylene-alt-propylene)-b-ethylene (PS/PEP/PE) triblock copolymers has been achieved on benzoic acid crystal substrate. The epitaxial relationship is similar to that obtained for the polyethylene homopolymer. For both copolymers uniplanar textures characterized by crystalline lamellae standing edge-on on the substrate are obtained. Electron diffraction patterns indicate that the polymer chains lie flat on the substrate surface, with the chain axis parallel to the a axis of benzoic acid. For the PE/PEP/PE copolymer the pattern correspond to the bc section of the reciprocal lattice of PE, the (100) plane of PE being in contact with the (001) plane of benzoic acid. Lamellar twisting, in particular rotation around the b axis, accounts for the presence of 1kl and 2kl reflections in addition to the expected 0kl ones. For the PS/PEP/PE copolymer the electron diffraction pattern corresponds to a fiber-like pattern, indicating rotation around the c axis as a result of lamellar twisting.

NP01 200 Characterization of low-dielectric poly–silsesquioxanes with Positron Annihilation Lifetime Spectroscopy A. FAIVRE, T.L. DULL, J. SUN, A.F. YEE, *Department of Materials Science and Engineering, University of Michigan, Ann Arbor, MI 48109* W.E. FRIEZE, D.W. GIDLEY, *Department of Physics, University of Michigan, Ann Arbor, MI 48109* C. NGUYEN, D.Y. YOON, *IBM Almaden Research Center 650 Harry Road, San Jose, CA 95120* As the scale of microelectronic devices is decreased, the dielectric constant of insulating materials becomes a major contributor to RC delay times. Polysilsesquioxane (poly-SSQ) films, (with dielectric constants $k \leq 3$) are being explored as possible replacements SiO_2 ($k \approx 4$). Little is known about the basic structure of poly-SSQs even in bulk form. As low-dielectric thin films, structure studies are hampered by a lack of submicron film probes. Positron Annihilation Lifetime Spectroscopy (PALS) has been applied to study several types of poly-SSQ including octaglycidyl-SSQ (OG-SSQ) epoxy and methyl-SSQ. Source-based PALS studies of OG-SSQ epoxy confirm a structure consisting of 5 Å rigid cubes embedded in a more flexible crosslinked network. Beam-based PALS has also been

applied to characterize submicron OG-SSQ epoxy films and methyl-SSQ films which are thought to form ladder structures. This work is supported by National Science Foundation grant ECS-9732804 and National Institute of Health grant 5-P50-DE09296-08.

NP01 201 Bridges vs. Loops in Ordered Triblocks: Dielectric Spectroscopy and Computer Simulations* K. KARATASOS, S. H. ANASTASIADIS, *FO.R.T.H.-I.E.S.L., Greece* T. PAKULA, *MPI-P Mainz, Germany* H. WATANABE, *Kyoto Univ., Japan* Dielectric relaxation spectroscopy and computer simulations have been used to probe the bridge fraction in ordered symmetric B-A-B triblock copolymers. The separation of loop- and bridge-contribution to the dielectric relaxation of a PS-PI-PS triblock having symmetrically inverted dipoles along the middle block is significantly affected by sample preparation/annealing, which may affect not only the bridge fraction but even more both bridge and loop dynamics. Computer simulations lead to the conclusion that at equilibrium the contribution of loops is almost twice that of bridges with both, however, having similar relaxation rates. The total intensity is much larger than for the respective diblocks, which agrees with the data for the annealed triblocks. The static information from the simulations agree with theory and with the data resulting in bridge fractions of 0.50-0.37. The dynamics of loops and bridges are found not very different from that of the diblocks in disagreement with the observation on the annealed systems.

NP01 202 Molecular Modeling of Polyhedral Oligomeric Silsesquioxanes (POSS) Based Polymers RISHIKESH K. BHARADWAJ, *Systran Corp.* SHAWN PHILLIPS, *Air Force Research Lab* JOSEPH D. LICHTENHAN, *Hybrid Plastics, Inc.* W. W. ADAMS, *Air Force Research Lab* B. L. FARMER, *Air Force Research Lab* The study of structure- property relationships in polymers based on Polyhedral Oligomeric Silsesquioxane (POSS) is a subject of ongoing research. Co-polymerization of POSS macromers into conventional polymers can lead to dramatic changes in properties, such as the glass transition temperature, mechanical, and transport properties. The large variety of functionalities that can be incorporated on the POSS macromers lend themselves to tailoring property/application specific polymers. Ab initio and semi-empirical methods have been used to aid in the development of force field parameters to describe these molecules for use in performing molecular mechanics and dynamics (MD) simulations. POSS macromers having methy, cylcopentyl or cyclohexyl substituents have been investigated in various geometries. The behavior of free individuals, linear tethers of various lengths, and four-arm star tethered macromers have been examined. The results of vacuum and bulk phase MD simulations indicate that the substituents serve dual roles of affecting persistent interaction between macromers while at the same time disrupting any ordered association.

NP01 203 Phase I/II Crystals of Poly(p-oxybenzoate): Effects of Substrate and Polymerization Conditions* F. RYBNIKAR, P. SAHA, *Fac. of Tech., Univ. of Brno, Czech Republic* B.-L. YUAN, P. H. GEIL, *Univ. of Illinois* The phase I/II crystal structure ratio of thin film melt polymerized PpOBA[a] is affected by the substrate; base treatment of glass and mica results in II while acid treatment of mica (not glass) enhances I and also reduces the development of epitaxially polymerized/crystallized[b] phase I polymer. In bulk melt polymerization II is nearly absent unless T_p is greater than 300°C (i.e. T_{k-m}). The changes are attributed to a substrate nucleating effect. For solution polymerization effects of T_p, t_p and concentration on I/II and morphology are shown. The morphology of the phases (and T_{k-m}) can not be distinguished, with II appearing to contribute to coherence of the discs and whisker-discs observed for certain solution conditions. T_{k-m}, however, depends strongly on the morphology, whiskers having T_{k-m} 30-40 °C greater than the discs, a T_{k-m} that is retained through several heating-cooling cycles. [a]. F. Rybnikar, et al., Macromol. Chem. Phys., 195, 81 (1994). [b]. F. Rybnikar et al., J. Polym. Sci., Polym. Phys. Ed., 35, 1807, (1997).

NP01 204 Time-Domain Spectroscopy Analysis of the Amorphous Phase in Semicrystalline Polycarbonate CHAD SNYDER, *NIST* FREDERICK MOPSIK, *NIST* HERVE MARAND, *Virginia Tech* AZAR ALIZADEH, *Virginia Tech* SEUNG MAN SOHN, *Virginia Tech* The amorphous state of bisphenol-A polycarbonate was examined by time-domain dielectric spectroscopy as a function of crystallization time over a frequency range of $1x10^{-4}$ Hz to $1x10^{4}$ Hz. The dielectric measurements were performed in the temperature range around the glass transition temperature. Dielectric studies were performed on a series of samples, which were partially melted and recrystallized so as to investigate the influence of ''secondary crystallinity'' on the alpha relaxation, thereby probing the effect of crystalline constraints on cooperative motions in the amorphous fraction. Analysis of the relaxation behavior was performed by fitting the loss max frequency data to the Vogel-Fulcher-Hesse-Tammann and Arrhenius equations. Fits to the Havriliak-Negami equation were performed with careful consideration of the conclusions made by two of us in a recent paper: C.R. Snyder and F.I. Mopsik, J. Appl. Phys., 84 (8), 4421 (1998).

NP01 205 Patterning of Self-Assembled Monolayers (SAMs) Using Synchrotron X-ray Radiation X.M. YANG, T.K. KIM, R.D. PETERS, PAUL NEALEY, *University of Wisconsin-Madison* The use of X-ray lithography to pattern self-assembled monolayers was investigated as a means to create surfaces with regions of different chemical functionality. Our long-term goal is to use advanced lithographic techniques to pattern regions with dimensions less than 100 nm. SAMs were prepared by the chemisorption of organotrichlorosilanes on SiO_x substrates, and were exposed to synchrotron X-ray radiation through a mask. Patterns of various shapes and lateral dimensions (0.2 to 50 μm) were transferred from the X-ray mask to the SAM surface over large areas. The SAMs remained intact on the surface for doses as high as 3000 mJ/cm^2. When SAMs of octadecyltrichlorosilane were exposed in the presence air, the contact angle of water monotonically decreased with dose from 110 to 25, and XPS data revealed the presence CHO and OH groups on the surface of the SAMs. Patterned SAMs were imaged with condensation figures and lateral force microscopy.

NP01 206 Sub-nanometer Defects near Polymer Surfaces Studied by Positron Annihilation RENWU ZHANG, *University of Missouri-Kansas City* HUIMIN CAO, *University of Missouri-Kansas City* JEN-PWU YUAN, *University of Missouri-Kansas City* HONGMIN CHEN, *University of Missouri-Kansas City* YING HE, *University of Missouri-Kansas City* THOMAS SANDRECZKI, *University of Missouri-Kansas City* Y.C. JEAN, *University of Missouri-Kansas City* BENT NIELSEN, *Brookhaven National Laboratory* R. SUZUKI, *Electrotechnical Laboratory, Japan* T. OHDAIRA, *Electrotechnical Laboratory, Japan* Sub-nanometer defects (free volumes and holes) near the surface of polymeric systems have been measured by using Doppler broad-

ening of positron annihilation radiation and positron annihilation lifetime spectroscopy coupled with a mono-energy positron beam. The positron annihilation results show the applicability of using positron annihilation spectroscopy to probe physical properties near the surface of polymers and to study degradation of polymeric coating systems under UV irradiation. Supported by AFOSR and NSF. H. Cao et al, J. Phys. Condens. Matter 10, 1(1998).

NP01 207 Diffusion in Porous Systems With Binding: Exact Results JOSE G. LABRIE, *University of Ottawa* GARY W. SLATER, *University of Ottawa* Our recently developed lattice model of particle diffusion in porous media can be extended to account for the presence of attractive particle-medium interactions. This algorithm is a very powerful numerical method, because it has the flexibility to include such interactions while still providing us with exact results in a much more efficient manner than the widely used Monte-Carlo simulations. We assign a negative local potential energy to each of the sites adjacent to an obstacle, and we use periodic boundary conditions. The study of the effect of attractive interactions on the reduced diffusion coefficient can be applied to various problems including: affinity electrophoresis, chiral separations, diffusion of colloidal particles in gels and polymer solutions, and the diffusion of proteins on cell membranes. The interplay between obstruction and enthalpic effects can lead to very interesting phenomena, especially for fractal media.

NP01 208 Effect of Hydrogen Bonding on Translational and Rotational Probe Molecule Dynamics in Polymers K.E. HAMILTON, D.B. HALL, J.M. TORKELSON, *Northwestern Univ., Evanston, IL 60208-3120 USA* The influence of hydrogen bonding on translational and rotational diffusion of small molecule probes differing in structure only by one probe having an S atom in place of an NH group on the second have been studied in polymers using second harmonic generation and fluorescence nonradiative energy transfer. Near Tg, the dynamics of the two probes are nearly identical in polystyrene which does not promote hydrogen bonding. However, in poly(isobutyl methacrylate), which accommodates hydrogen bonding with the NH group, rotational and translational diffusion are typically an order of magnitude or more slower for the probe which can hydrogen bond. Translational diffusion of both probes may be represented by Vrentas-Duda free volume theory, taking into account the energy of interaction due to hydrogen bonding. However, rotational diffusion cannot be adequately accounted for by simple activation energy effects due to hydrogen bonding. This may be due to an increase in the size scale of local cooperativity involved in probe rotation for hydrogen bonding systems.

NP01 209 Preparation of Poly(styrene-co-methyl methacrylate) Multiblock Copolymers via Atom Transfer Radical Polymerization ERIC EASTWOOD, DAN MARTINEAU, MARK D. DADMUN, *Chemistry Dept., University fo Tennessee, Knoxville, TN 37996* The synthesis of multiblock copolymers is difficult with conventional synthetic techniques. These difficulties arise from the inability of one monomer to initiate the polymerization of the other monomer. This common limitation is observed with polystyrene and poly(methyl methacrylate) copolymers. Atom transfer radical polymerization is a method that may prove useful in the preparation of multiblock copolymers. This technique has been used to synthesize triblock copolymers of styrene (S) and methyl methacrylate (MMA) using phenoxybenzene-4'4' disulfonyl chloride with a copper(I) chloride/ bipyridine complex as the initiator. To monitor the kinetics, the molecular weights of periodically removed samples were monitored by size exclusion chromatography. Results indicate that the addition of MMA onto S is more efficient than the addition of S onto MMA. Further investigations will expand this study to a larger number of blocks and also examine the effect of heterogeneous verses homogeneous initiation on the synthesis of multiblock copolymers.

NP01 210 Biological Hydroxiapatite coatings by Pulsed Electron Beam Deposition VICTOR FUENZALIDA, *Universidad de Chile* PABLO NAVARRETE, *Universidad de Chile* CARLOS GRAHMANN, *Universidad de Chile* Thin films of biologic hydroxiapatite were deposited on titanium and silicon substrates. The source was human teeth, previously cut in a slice, polished, and heated in air at 150 degree for 3 hours to remove excess water. A plasma discharge in oxygen at 1 Pa generates an electron pulse, which is accelerated at 15-16 KeV onto an area of 1 mm2 on the target. The discharge lasts for about 100 ns, leading to nearly stoichiometric ablation of the target material. SEM micrographs of the films revealed a rough surface with grains up to 1 micrometer. The thickness was determined by profilometry, after defining a step and etching with HNO3, giving an average value of 280 nm, with minimum thickness of 120 nm, maximum of 682, and a rms. roughness of 110 nm. The film composition was analyzed by x-ray photoemission spectrometry. Preliminary dissolution experiments in the ultrasonic bath indicate dissolution in deionized water only at the thinnest regions of the films.

NP01 211 The Work of Adhesion of Polymer/Wall Interfaces and the Onset of Wall Slip* S. G. HATZIKIRIAKOS, *Univ. of British Columbia, Canada* S. H. ANASTASIADIS, *FO.R.T.H.-I.E.S.L., Greece* The interfacial characteristics of a variety of polymer/wall interfaces were measured by using the sessile drop method in order to calculate the work of adhesion. Polymers included linear low-density- as well as high-density- polyethylenes, while wall substrates included clean stainless steel and modified stainless steel by applying two different fluoropolymers in order to alter its surface energy. A linear correlation is found between the critical shear stress for the onset of slip and the work of adhesion of the corresponding polymer/wall interface, in agreement with the earlier predictions, which are used to interpret the experimental results. It is suggested that small deviations from the no-slip boundary condition in the case of polymer melts flow are due to a stress induced chain detachment / desorption of polymer chains from the wall.

NP01 212 Self Diffusion of a Semiflexible Polymer Measured Across the Lyotropic Liquid Crystalline Phase Boundary GARRETT DOUCET, *Louisiana State University* PAUL RUSSO, *Louisiana State University* MICHAEL BAYLIS, *Louisiana State University* ZIMEI BU,* *Louisiana State University* WIESLAW STRYJEWSKI, *Louisiana State University* ELENA TEMYANKO, *Louisiana State University* DEBBIE TIPTON,† *Louisiana State University* The self diffusion of fluorescently tagged poly(benzylglutamate), a helical, semiflexible synthetic homopolypeptide, has been measured in isotropic and cholesteric liquid crystalline solutions by pattern fluorescence photobleaching recovery. On the isotropic side of the sharp ISO-LC phase boundary, the rodlike polymers assume all possible orientations in a three-dimensional space, becoming enmeshed. In liquid crystalline so-

lutions, as first shown by Robinson (Trans.Faraday Soc., 52, 571-592, 1956), spontaneous alignment of the cholesteric screw axis parallel to the optical (z) axis of the instrument produces small monodomains in which parallel rodlike polymers are organized into planes. Each horizontal plane is twisted slightly compared to its neighbors. Over the thickness of the sample, the rodlike polymers assume all possible orientations in this two-dimensional space. Despite the small size of the monodomains, it was possible to determine the self diffusion coefficient of the semiflexible rods, orientationally averaged in two dimensions. Crossing the sharp ISO-LC phase boundary corresponds to the sudden release of any putative topological constraints active in the isotropic phase, and produced a modest but significant increase in diffusion. A relationship developed by Hess, Frenkel and Allen (Mol.Phys., 74(4), 765-774) is used to show that diffusion perpendicular to the rod axis is about 10 times slower than diffusion parallel to the rod axis in the liquid crystalline phase. In dilute solution, the comparable number would be 2. The perpendicular diffusion had decreased to about 8% of its initial value in dilute, isotropic solution. The parallel diffusion decreased to about 40% of its initial value.

NP01 213 Deformation of Ionic Hydrogels Under Electric Fields LI YAO, SONJA KRAUSE, *Department of Chemistry, Rensselaer Polytechnic Institute, Troy, NY 12180* Previously, we had found a reversible gel bending phenomenon of a partially sulfonated (50 % sulfonation) triblock copolymer gel of styrene-ethylene/butylene-styrene (S-SEBS) in low DC electric fields[1]. However, the life-time of the gel in the experiments was limited by the lack of chemical crosslinks in the network. Therefore, a series of crosslinked S-SEBS gels were prepared by gamma irradiation. The bending behavior of the crosslinked gels in electrolyte solutions was qualitatively similar to that of previous studied S-SEBS gels. Quantitative analysis of the bending of crosslinked S-SEBS gels as function of gel crosslink density, electrolyte cation size and concentration will be reported. In addition, the bending of a partially sulfonated crosslinked PS gel will also be discussed. By studying the bending kinetics, we tentatively believe that the bending is due to differential swelling between the two sides of the gel strip. The mobility of the cations in the system is the key to this electromechanical response. This work was supported by ONR and NSF (Grand No. DMR-9521265.)

NP01 214 Heat Capacity Anomaly in Succinonitrile and Water MADHUJIT GHOSH, *The College of Wooster, Wooster, Ohio* SHAUN McCLELLAN, *Mount Union College, Alliance, Ohio* D.T. JACOBS, *The College of Wooster, Wooster, Ohio* The heat capacity at constant pressure has been measured in the near-critical, binary fluid mixture succinonitrile and water. Our adiabatic calorimeter used a computer-based data acquisition and control system and determined the heat capacity in the one- and two-phase regions from multiple runs within five degrees of the critical temperature (329K). The anomaly in the heat capacity can be characterized by a simple scaling relationship using the critical exponent alpha as 0.11. The resulting amplitudes allow universal relationships to be tested. Acknowledgment is made to the donors of The Petroleum Research Fund, administered by the ACS, for support of this research.

NP01 215 Effect on the dielectric relaxations of substitutions in the mesogenic unit and the flexible spacer of main chain liquid crystal polyesters A. BELLO, M.C. HERNANDEZ, E. LAREDO, *Universidad Simón Bolívar, Caracas, Venezuela* M. A. GOMEZ, C. MARCO, *Instituto de Ciencia y Tecnología de Polímeros, C.S.I.C, Madrid, Spain* The asymmetrical substitutions either in the tetramethylene spacer and/or in the mesogenic unit of a main chain thermotropic liquid crystal polyester, has important consequences on the dielectric relaxations studied here by Thermally Stimulated Depolarization Currents (TSDC). By comparing the TSDC spectra given by the four polymers the effect of the chlorine substitution in the external rings of the mesogenic unit slightly affects the position of the low temperature relaxation modes but reverts the relative intensity of the peaks forming this multicomponent band, favoring the most energetic one. The addition of the methyl groups in the flexible spacer enhances the intermediate relaxation. The different modes as temperature increases are assigned to the localized reorientations of the COO peripheral groups, and to the internal COO for the two higher modes. The α-transition is shifted to higher temperatures in presence of methylene substituents which reduce considerably the molecular chain mobility, and its high intensity shows the absence of crystalline order. In the presence of Cl substituents the relaxation times for the cooperative motions which originate the α-mode, shows a wider distribution attributed to the multiphase character of these materials.

NP01 216 Adhesion at Model Polymer Interfaces* RICHARD P. WOOL, KEITH A. WELP, LEIZHONG GONG, ILSOON LEE, *Department of Chemical Engineering, University of Delaware, Newark DE 19716-3110* We investigated the structure-strength relations for model interfaces containing selectively deuterated polymers, and polymer-solid interfaces with controlled number of sticker groups adhering to surfaces of known receptor site density. The interface structure was determined by Neutron Reflectivity, DSIMS, XPS and AFM. The fracture energy G, was determined by the J-Integral methods applied to the deformation zone containing the interface at the crack tip. Time dependent weld structure results were obtained which confirmed the reptation dynamics model proposed by P.-G. DeGennes. New vector percolation models of adhesion were developed and found to be the key to relating structure to strength of the weak boundary layer observed for polymer-solid interfaces.

NP01 217 Relaxation Dynamics of Polymer Chains in Rubbed Thin Films Probed Using Linear and Nonlinear Optical Techniques DENA M. AGRAB, *Kent State University* J.-H. KIMB, *Kent State University* ALEXANDER SCHWAB, *University of Akron* SATYENDER KUMAR, *Kent State University* ALI DHINOJWALA, *University of Akron* Rubbing of polymer surfaces is used in aligning liquid crystals in the manufacturing of displays. It has been shown to induce orientation of the surface chains along the direction of rubbing which is lost on heating close to the glass transition temperature of the polymer, Tg. The mechanism of this disorientation and how it is influenced by the structure of the polymer chain is poorly understood. We have employed a sensitive birefringence and sum frequency generation to probe the dynamics of this reorientation process in polystyrene (PS), polymethylmethacrylate (PMMA), and polyimides (PI) systems. Since the side group in PS dominates the birefringence, this offers an

opportunity to understand the influence of side group motion on the surface dynamics. For the case of lightly rubbed PS upon heating at a rate of 1K/min, the birefringence begins to decrease at 70oC and reaches zero at 100oC. This is reminiscent of the motion associated with the Tg and in qualitative agreement with previous studies using NEXAFS. The influence of the film thickness on the dynamics of surface reorientation and consequently the influence on Tg, will be discussed.

Events at a Glance - Georgia World Congress Center

Saturday March 20th

- 1:30 – 3:00 p.m. **Grand Opening: Nobel Discoveries** Exhibit/Reception (Registration Hall)
- 3:00 – 6:00 p.m. **Symposium on International Science Cooperation** (Conference Center)

Sunday March 21st

- 9:00 a.m. – 12:00 noon **Int'l Workshops/ Roundtables**
- 1:00–1:45 p.m. **Opening Centennial Session** (Ballrooms)
- 2:00 – 5:00 p.m. **Centennial Symposia and Scientific Sessions**

Monday March 22nd

- 8:30 – 10:00 a.m. **Plenary Keynote** (Ballroom)
- 10:00 – 11:50 a.m. **Public Physics Talks** (Auditorium)
- 10:30 a.m. – 1:00 p.m. **Centennial Symposia and Scientific Sessions**
- 10:00 a.m. – 1:00 p.m. **APS Units Expo** (Hall D)
- 1:00 – 5:00 p.m. **APS Units Expo** (Hall D)
- 1:15 – 3:45 p.m. **Centennial Symposia and Scientific Sessions**
- 4:00 – 6:00 p.m. **Plenary Session** (Ballrooms)
- 6:30–8:30 p.m. **Welcome Reception**

Tuesday March 23rd

- 8:00 – 10:30 a.m. **Centennial Symposia and Scientific Sessions**
- 10:00 – 11:50 a.m. **Public Physics Talk** (Auditorium)
- 10:30 a.m. – 1:00 p.m. **Centennial Symposia and Scientific Sessions**
- 1:00 – 6:00 p.m. **APS Units Expo** (Hall D)
- 1:15 – 3:45 p.m. **Centennial Symposia and Scientific Sessions**
- 4:00 – 6:00 p.m. **Plenary Session** (Ballrooms)
- 6:00–8:30 p.m. **Grand Reunion**

Wednesday March 24th

- 8:00 – 11:00 a.m. **Centennial Symposia and Scientific Sessions**
- 10:00 a.m. – 3:00 p.m. **APS Units Expo** (Hall D)
- 10:00 – 11:50 a.m. **Public Physics Talk** (Auditorium)
- 11:00 a.m. – 2:00 p.m. **Centennial Symposia and Scientific Sessions**
- 2:00 – 5:00 p.m. **Centennial Symposia and Scientific Sessions**
- 5:15–7:00 p.m. **Awards/ Past President Address**

Thursday March 25th

- 8:00 – 11:00 a.m. **Centennial Symposia and Scientific Sessions**
- 11:00 a.m. – 2:00 p.m. **Centennial Symposia Scientific Sessions**
- 2:00 – 5:00 p.m. **Centennial Symposia and Scientific Sessions**

Friday March 26th

- 8:00 – 11:00 a.m. **Centennial Symposia and Scientific Sessions**
- 11:00 a.m. – 2:00 p.m. **Scientific Sessions**
- 2:00 – 5:00 p.m. **Scientific Sessions**

1999 Centennial Meeting Corrigenda

As of March 10, 1999

(Please consult the on-site board of changes for additional updates.)

Preamble/Social Activity Changes

•Companions' Breakfast	Moved to Barrington Hall, Omni Hotel
•CCP99 Reception	Day changed to 3/25, 18:30, Thornton Room, Omni Hotel
•Annual Run for Health	Participants meet at the Westin Hotel
•International Reception	Moved to the Plaza Ballroom, Westin Hotel
•Students' Luncheon	Moved to Exhibit Hall E, GWCC
•Texas Section Luncheon	Canceled

Program Changes

•DA00.01	Science Policy at the Presidential Level	Renamed CA01, moved to 08:30, 22 March, Ballroom, GWCC
•Keynote Address	Hon. Bill Richardson, Secretary of Energy Jerome Friedman, MIT Arun Netravali, Lucent Technologies Robert Eisenstein, NSF Chair, Jerome Friedman	Moved to 19:30, 22 March Ballroom, GWCC

Session Assignment Changes

Original Placement	*New Placement*	*Title*	*Author*
•GP05.01	KP01.136	Electrical and Optical Properties of New Polynaphthalene Networks	H. Shah D.W. Smith, Jr.
•VP05.43	LB12.04	The Year One Physics Capabilities of STAR	H. Caines

Time Changes

•DAP	Business Meeting, following Session LB01	23 March 1999, 15:45 Room 201E, GWCC
•LA02.01	The Evolution of Accelerators and Colliders for High Energy Physics (W.K.H. Panofsky)	3/23, 13:51
•LA02.02	What Did You Do in the War, Daddy? Physicists' Experience in World War II (R. Seidel)	3/23, 13:15
•OC19.04	Finding Transition Pathways in Complex Systems, with Applications to Liquid State Chemical Dynamics (P. Bolhuis, et al.)	3/24, 9:12
•QB22.01	Highly Charged Ion Collisions: From Atoms via Clusters to Surfaces (H. Cederquist)	3/24, 12:12
•QB22.02	X-Ray Charge Transfer Measurements Involving Low-Energy Highly-Charged Ions (P. Beiersdorfer)	3/24, 12:48
•QB22.03	Momentum Imaging of Ion-Atom and Ion-Molecule Collisions (R.E. Olson)	3/24, 11;36
•QB22.04	Ongoing Renaissance of Study and Application of Ion-Atom Collisions (D. Schultz)	3/24, 11:00

Time Changes

•SC36.01	Spin-Polarized Tunneling between Ferromagnets and Photoexcited Semiconductors (R. Jansen)	3/24, 15:48
•SC36.04	Early Results in Spin-Polarized Tunneling (P.M. Tedrow)	3/24, 14:00
•VC35	Session: Many-Body Interactions in Quantum Dots	14:00 Ballroom II
•WC34.05	Incorporation of Nitrogen at Si-Dielectric Interfaces for Advanced Device Structures (G. Lucovsky)	3/25, 16:24

Speaker Changes

•BA02.02	Hon. Rush Holt replaces Sen. Joseph Lieberman
•GP01.163	Martin St.-Hilaire replaces Andre Longtin
•JB07.01	Dana Partos replaces Joey Huston
•QA01.04	Chris Bardeen replaces Kent R. Wilson
•UC33.10	Brian Setlik replaces Michael Tammaro
•VC17.10	Ken Segall replaces A.K. Davies

Abstract Additions

•IB13.12	Hydrogen Atom in Strong Magnetic Fields: Hidden Crossings Approach (P. Krstic)
•OC02.12	Electron-phonon effects on an armchair SWNT (L. Woods, G.D. Mahan)
•VP05.116	Radiation Effects of SiC Diodes (D.T. Shi)
•VP05.117	Single Organic Molecules as Electronic Devices (A.G. Zacarias, J.M. Tour, J.M. Seminario)
•WC19.03	Electronic Structure of Dipole-Bound Anions and Solvated Electrons (M. Gutowski, P. Skurski)
•WC44.117	Synthetic Dielectric Material for Broadband-Selective Absorption and Reflection (W. Janos)
• WC44.118	Theoretical Studies of the Isotope Effect in the C_{60} Molecule (A. Calles, J.R. Soto, J.L. Morán-López)

Abstract Corrections

•BC13.03	Title changed to "Status Report of Direct CP Violation with the NA48 Experiment at CERN"
•BC36.09	First author and presenter is F.J. Cadieu
•FA01.03	Title is "Accelerators and High Energy Physics"
•FB04.05	Authors' names are Giovanna Selvaggi, Andrew Tate
•JC13.09	First author and presenter is C. Lacabanne
•LB10.05	First author and presenter is Mark Miller
•QB01.05	First author and presenter is G.C. Duncan

Session Chair Changes

•FC25	No chair for this session
•HA01	George H. Trilling, Lawrence Berkeley Laboratory
•IC17	A. M. Glass, Bell Laboratories, Lucent Technologies
•JC15	David Citrin, Washington State University
•MA02	James S. Langer, University of California, Santa Barbara
•OB01	Barbara Welther, Center for Astrophysics, Harvard University
•OB12	Keith Baker, Hampton University
•ZC17	No chair for this session

Author Index Changes

•Giovanna Selvaggi, Andrew Tate	Authors' names were incorrect

Withdrawals

DP01.133	Exploring the Folding Funnels of an Off-Latice Minimalist Funnel (M.S. Cheung)
DP01.160	Disproportionation of Wustite Studied by Mossbauer Spectroscopy (Y. Takagi)
EB05.04	The Brave New World of M Theory (J. Lykken)
EC12.02	Size and Density Segregation in Chaotic Granular Flows (K. Hill, et al.)
EC30.02	Temperature-frequency Scaling in Metallic, Critical, and Insulating Amorphous Alloy Films near the Metal-Insulator Transition (W. Henderson)
FB12.03	Beyond Monotony in Heavy Ion Physics: Signatures of the QCD Tricritical Point (K. Rajagopal)
FC02.04	A Method for Solving First-Order, Autonomous Ordinary Differential Equations (L. Robinett)
FC02.07	A Learning Algorithm for the Job-Shop Scheduling Problem (L. Cheng, K. Chen)
FC14.06	Critical Flow Conditions for the Rupture of Flocs (S. Blaser)
FC18.11	Density Functional Approach to Van der Waals Interactions - a Self-Consistent Scheme (T. Choy)
FC23.11	Growth and Dislocation Study of Layered $BiSbTe_3$ Single Crystals (C.F. Desai, S. Dhar)
GP05.51	Temperature and Angle Dependent Magnetization Peaks in Er123 Single Crystals (M.A. Avila, R.A. Ribeiro, O.F. de Lima)
IB04.01	Color Superconductivity (K. Rajagopal)
IC08.04	In-Situ X-Ray Diffraction Study of an Electric Field Induced Phase Transition in a Relaxor Ferroelectric Single Crystal (M.K. Durbin, et al.)
IC20.09	Repulsion of Fundamental Edge Magnetoplasmons at Integer Filling Factors and Nonlocal Response (P. Vasilopoulos, O. Balev)
IC21.01	Strain-induced Quantum Dots in Semiconductors (J. Davies)
IC27.03	Extended Electric Field - Current Density Characteristics of YBCO Coated Conductors (L. Schwartzkopf, et al.)
IC29.09	Gauge Field Fluctuations and Antiferromagnetic Correlations (P. Monthoux, P.A. Lee)
IC30.04	Diffusional Droplet Growth in Semi-Infinite Wetting Systems (R. Burghaus)
IC31.01	On the Elasticity Theory of Single DNA Molecules (M. Mezard)
JC13.11	Nonequilibrium Polymer Physics: Molecular Motors Fluidize Polymer Gels (D. Humphrey, et al.)
JC23.04	Hydrogen-assisted Laser Induced Transfer of Materials (D. Toet)
JC28.11	Green Function Method for the Dielectric Breakdown Problem (H. Lau, K. Chen)
KP01.136	Stark Shifting of Surface States in Silicon Field Emitters and its Impact on the Electron Tunneling Probability (S. Sood)
LB09.02	Four Fermion Events and Observation of Resonant ZZ Production at LEP (L3 Collaboration)
LB12.04	"Day 1" Physics with STAR (J. Harris)
LC05.07	The Magnetic Inhomogeneous State of Low Doped La_1-xCa_xMnO_3 Studied by Neutron Scattering (M. Hennion, et al.)

Withdrawals

NP01.85	An Automatic Impedence Measurement System for Detecting Superconducting Transitions via Magnetic Screening (D. Medeiros, C. Oliveira)
OB04.04	Current Mode Nertron Beam Flux Measurement with a ^{3}He Ion Chamber (C.S. Blessinger, et al.)
OB08.06	Search for Single Top Quark Production in the e+jets Channel (A. Heinson)
OC17.03	Characterization of Bimetallic Cantilevers for Chemical Sensor Application (S. Choi, et al.)
OC19.03	Molecular Dynamics of Rare Events (G. Ciccotti)
QB08.07	Search for Time Reversal Violation Using Muon Polarization in Charged Kaon Decays (A. Carroll, et al.)
QB09.10	Measurement of the \Lambda_b Lifetime Using Semileptonic Decays (P. Chang)
QC26.04	Resonant Inelastic X-ray Scattering Study of Ca2CuO2C12 (M.Z. Hasan, et al.)
QC31.04	Protein Design by Optimizing the Energy Landscape (M. Betancourt, D. Thirumalai)
QC31.07	Density Functional Theory of Antiferromagnetically Coupled Binuclear Iron Centers: Electronic Structure of Models for Diiron-Oxo Proteins (J.H. Rodriguez)
QC33.10	K/Si Absolute Coverage Via Rutherford Backscattering Spectroscopy (W. Sherman, R. Banerjee, N.J. DiNardo, W. Graham)
RP01.36	Beam-Laser Lifetime Measurements for Singly-Ionized Rare Earth Elements (E.H. Pinnington)
RP01.63	Studies in the Search for Supersymmetric Particles with Lifetime (R. Hossain)
SB08.02	Inclusive Vertex-Based Method for a B _d^0-\barB_d^0 Flavor Oscillation Measurement Using Semileptonic B Decays in p\b ar p Collisions at \mbox\sqrts = 1.8\mbox\,TeV (T.R. Shah)
SB08.06	Identification of Electrons in Jets at D0 (C. Hebert)
SC17.01	A New Formula for Restoration of Telegraphic Waveform (S.K. Foong, S. Kanno)
UB07.07	Large Gauge Invariance at Finite Temperature (G. Dunne)
UB08.12	Search for the flavor changing neutral current B-meson decays B^+\rightarrow \mu^+ \mu^- K^+, B^0\rightarrow \mu^+ \mu^-K^*0, and B^0_s\rightarrow \mu^+ \mu^- \phi at CDF (T. Speer)
UB12.05	LEXUS-Linear Extrapolation of Ultrarelativistic Nucleon-Nucleon Scattering (S. Jeon)
UB15.04	Dynamics Response of Solar Heated Buildings (V. Brown, K. Mallory)
VB09.06	Results from Fermilab E835 on Two Photon Decays of Charmonium Resonances (T. Pedlar, M. Stancari)
VC17.14	Lightweight, Temperature-insensitive, High Precision NMR/EPR Magnet (Kem E. Robinson, et al.)
VC25.07	Dissipation and the Superconductor-Insulator Transition (K. Voelker)
VC28.04	Numerical Study of Temporal Correlations in Model Earthquake Sequences: Comparison of Long-Range and Short-Range Models (S. Chia, K. Chen)
VC28.05	Variation of the Volterra-Lotka Model of Population Interactions: Time Dependent Interaction Parameters (E. Corona-Organiche, E. Lopez-Cruz)
VC33.07	In Situ Scanning Probe Microscopy of Electrochemical Copper Deposition on Si(111) (P. Hoffman)
VC36.08	Characterization and Growth of Several Geometrically Frustrated Pyrochlore Crystals (Jason S. Gardner, et al.)
VP05.25	Can One Live without Pseudopotentials? (B. Farid, C.J. Pickard, M.C. Payne)
VP05.046	Infrared Spectroscopy of Negatively Charged Water Clusters: Evidence for a Linear Network (P. Ayotte, et al.)
VP05.066	Photoluminescence of Sub-Micron Structures Containing Self-Organised InAs Quantum Dots (K.L. Schumacher, et al.)
WC10.01	GW Self-Energy Calculations Using the Space-Time Method (L. Steinbeck et al.)
XC21.05	Weak-Localization Corrections to the Conductivity of Double Quantum Wells (O. Raichev, P. Vasilopoulos)
XC24.02	Whispering Fluxons in Annular Josephson Junctions (A. Wallraff, A. Yulin, V.V. Kurin)
XC32.09	The Optical Stretcher - A Novel Tool to Measure Cell Elasticities (J. Guck, J. Kas)
YB15.13	Applications of Kohn-Sham Density Functional Theory to Molecular Magnetism: Direct Exchange and Super Exchange in Transition Metal Complexes (J.H. Rodriguez)
YC08.12	Turbulence Measurement in the Sargasso Sea Using an AUV Platform (M. Dhanak, K. Holappa)
YC19.07	The Interaction of Ammonia with Small Iron Clusters: Density Functional Calculations and Infrared Spectra (K. Jackson, M. Knickelbein, G. Koretsky)
YC31.04	Polarization of a Two-Dimensional Salt Solution Due to the Presence of Charged, DNA-like Molecules, and the Resulting Screened Fields and Interactions (R. Menes, P. Pincus)
ZC18.06	First Principles Investigation of Condensed Phase HMX (J.P. Lewis)
